The purpose of this book is to introduce scientists to the use of various highly sensitive micromethods and their application to the broad field of molecular biology. The methods are described in great detail, so that any experimenter can adapt them to his own field of interest. New, unpublished methods and results from the authors' laboratories are included. In essence, this is a "cook book," giving all the normally unpublished information which is necessary for the successful application of micromethods.

Detailed "recipes" are given for: micro-disc electrophoresis, micro-electrophoresis on gradient gels, micro-electrophoresis on SDS gradient gels, micro-isoelectric focusing, assay of DNA and RNA polymerase and dehydrogenases in microgels, micro-determination of amino acids with dansyl chloride, micro-determination of phospholipids, micro-diffusion techniques, capillary centrifugation, microphoresis of DNA and RNA bases, dry-mass determinations, microphotometry, cytofluorometry, quantitative autoradiography and several supplementary methods.

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.

- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).

- 'Matters arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. $\exp(a)$ is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of *Nature*. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in *Nature* (246, 238; 1973).

Opiate agonist-antagonist effects on Renshaw cells and spinal interneurons—

100 years ago

WE take the following from the *Academy*:—"Some of the American papers state that Prof. Huxley is likely to be the successor of Prof. Agassiz, at Harvard. We hope there is no truth in this. Are the English Universities so rich in really eminent professors, and so poor in money, that they can or must allow Prof. Huxley to go to America in order to find leisure for work? It would require nothing but the will for either Oxford or Cambridge to offer Huxley two or three thousand a year, without anybody suffering for it. There are hundreds of non-resident Fellows, doing no good to the University, doing harm to themselves in resting on their oars, when they ought to be pulling with all their might. Why not give five or ten such Fellowships to men like Huxley, and make the Universities again what they were in the middle ages, the very centres of intellectual force and light in the country? The Universities are so rich that they could beggar the whole world. Will they allow themselves to be beggared by Harvard?"

From *Nature*, 10, 195, July 9, 1874.

How Britain spends its research and development money

Sources

Advisory Board for the Research Councils, First Report, Appendix V, Table 1, June 1974.

Memorandum by the Chief Secretary to the Treasury, 1974/75.

Adjustments have been made to 'de-Rothschild' research council expenditures for the past two years.

Chilean scientists remaining in the country are labouring under very difficult circumstances which are mainly economic. Funds for research are very limited, and it is very difficult for these people to carry out experiments using modern techniques.

From Carlos Eyzaguirre, Chairman of the Department of Physiology, University of Utah College of Medicine, Salt Lake City, and Visiting Professor, Department of Neurobiology, Catholic University of Chile, Santiago.

I READ with interest a letter (*Nature*, March 29) signed by H. M. Gerschenfeld and others, regarding the situation of the academic community in Chile. It is intriguing and provoking since it shows a rather desperate situation: instances of police brutality, wholesale dismissals of faculty and students and a total disregard for academic freedoms and human rights on the part of the military government. The letter is inaccurate and the charges very serious. Thus, a reply is in order.

I started my academic career in Chile and went permanently to the United States about 17 years ago. Since then, I have returned to Chile many times for academic purposes and have continuously maintained close contacts with Chilean academics. At present I am a Visiting Professor of Neurobiology at the Catholic University and have been in the country since April. Thus, I feel better qualified to judge the present situation than the gentlemen signing the letter to *Nature*.

Dr Allende's Government started with high hopes for the underprivileged who are numerous in this country. Unfortunately, slowly and steadily things deteriorated to the point of chaos and anarchy. The universities were not immune to this decaying process: funds were drastically cut to the point where research came to a standstill. CONICYT (equivalent to the National Research Council), which actively supported research during the previous Frei administration, became a planning agency which developed a number of programmes more often than not politically motivated. The Academy of Sciences of the Instituto de Chile was left practically without funds. There was total lack of student discipline to the point where it was extremely difficult to conduct normal academic activities. In addition, there were frequent armed confrontations on the streets, incredible government corruption and, near the end, people had to queue for hours to get a few

essentials such as bread, soap, fuel, cigarettes. In the middle of this lovely picture the military struck with vigour on September 11, 1973. Interestingly enough they were shot at by supposedly defenceless civilians. In the melee many people were killed (including soldiers and policemen) and mopping up operations continued for a while. In context, the military operation in Chile was not a palace coup but a civil war which, fortunately, lasted only a few days. Casualties were many, but they could have been much more numerous if the military had been less decisive.

No one denies that there have been mistakes, cases of police harshness and unfair firing of people from their jobs. Some of these unpleasant practices have, however, been corrected; the country is again at work with the consequent increase in productivity, there is more discipline and normal activities have resumed. The people have co-operated, not necessarily because of fear, but the coup had the acceptance of the majority of the people. In a country like this, with a profound democratic tradition, nobody can govern without popular acquiescence. The democratic process has not been restored yet. Congress and the political parties are in recess and the press is still quite cautious. There is, however, hope for the future and the military have promised full democracy as soon as possible, whenever that may be. Many people believe that these are not vacuous statements since the military in Chile have been and are civic minded. Proof of this is that they have supervised all elections since 1938, when under President Pedro Aguirre (head of a Popular Front coalition) they got that authority. This practice continued under Dr Allende and there is consensus that elections in Chile have been generally fair.

Why did the military strike? They did so to restore the country to a more normal way of life, to eliminate the unconstitutional excesses of the previous government and the political, moral and economic chaos present in Chile at that time.

It was not an easy task, from a public relations point of view, since Dr Allende enjoyed great popularity in foreign countries. He was pictured as a democrat trying to reach socialism by peaceful and constitutional means,

a David fighting the United States Goliath and opening new ways of government to improve the lot of the poor; in short, Sir Galahad under a poncho. Most of his countrymen saw him in a different light: a scheming, corrupt and manouevering politician trying to outflank the wishes of Congress and of the Courts and bribe the Armed Forces, and very incompetent in the business of running the country. Moreover, they resented the fact that Dr Castro and the Soviet Union had too much to say about national affairs. Some of these complaints were unfair since there was political and economic pressure from the United States and he had to turn somewhere for help. The fact remains, however, that he could not manage the affairs of the nation and Chile would have faced certain economic, moral and political ruin had he remained in power.

Soon after the military coup, the heads (rectors) of the different universities were fired by the government. They were replaced by retired senior armed forces officers. Also, an army general was made head of CONICYT. These appointments seem, on the surface, to go against traditional university procedures, at least in Chile where most university presidents have been academicians. In other countries such as the United States, university presidents vary from academic to scientific administrators (such as Dr Fletcher at the University of Utah and now head of NASA) or retired politicians or generals (Eisenhower at Columbia). Thus, the appointments of Admiral Swett as Rector of the Catholic University or General Ruiz at the University of Chile would not be too far from practices that are not unknown in the United States. The difference is that both Admiral Swett and General Ruiz were appointed very soon after the military takeover in Chile. Interestingly enough, Admiral Swett's appointment was confirmed by Cardinal Silva, head of the Catholic Church and Chancellor of the Catholic University.

The new university rectors faced several problems: (1) an unruly student body heavily loaded with Marxist activists. Some of them were not students in the traditional sense of being properly registered, attending classes, taking examinations and so on; (2) a

peculiar faculty, some members being almost exclusively interested in the propagation of Marxism and organising revolutionary and guerrilla activities. Some did not even have a BA degree. This situation became intolerable for some faculty members who left the country and sought employment abroad; (3) chaotic finances which prevented normal university activities and the payment of adequate personnel salaries. One wonders if any university in a civilised country would have tolerated that situation for long.

The rectors had to act and they did the following: (1) students at some universities had to re-register. Students who did not qualify as such in the traditional sense (taking a certain number of courses for credit, passing qualifying examinations and so on) were dismissed. This weeded out the purely political 'students', but is this so terribly unfair? At the Catholic University, however, all of 11,500 students remained and no one was required to re-register. (2) The faculty went through the same screening procedure. Those who did not qualify for lack of degrees or for being exclusively political activists were dismissed. This procedure would have been applied in any university under normal circumstances. Left-leaning faculty members who carried out their duties of teaching and research during Allende's government were not asked to resign. Many of them are still in Chile. Some have left because of their inability to come to terms with the present government. This is their prerogative and their exit from the country has not been impeded.

Wholesale executions of faculty or scientists because of political views have not occurred. Very few fell either immediately after or during the coup because, allegedly, they were caught either shooting at soldiers, carrying arms or actively participating in the organisation of revolutionary activities. For the past several months, however, there has been no indication that such a thing has occurred again. Some academicians, deeply involved in extremist activities were detained for investigation. Most of them have been freed and many have returned to jobs in the same or different universities. Others have either not returned to the country or have sought asylum. There

Rector Ruiz

are charges against some of these people and if they return they will face legal prosecution. But prosecution is one thing and persecution another. Some academicians have had trouble with the police because of denunciations by neighbours or colleagues. These people have been investigated and, if cleared, they have been employed again in the same or similar jobs.

The question is then, what constitutes an offence leading to academic dismissal that would prevent further academic employment? I am not privy to the deliberations of the rectors, but it is my opinion that such an offence would be a deliberate effort on the part of an individual to topple the present government by either propaganda or more violent means. In other countries these activities are not looked on with favour by the governments involved. Thus, it is asking rather too much of the present Chilean government to tolerate these activities, particularly since the military came to power only a short time ago and after a rather messy civil war. This deals directly with a statement in the letter to *Nature* regarding the Catholic University. The statement is inaccurate. Only 3.25% of faculty members were removed after the coup because they did not do teaching and research but engaged exclusively in different forms of political activity. To assume that the rest (96.75%) were all right-wing, God-fearing, church-going and thoroughly nice fellows would be naive in the extreme. In fact, many of them have views that would not please the present government. But Admiral Swett has been a careful, intelligent and conscientious administrator who

has strived very hard to maintain and improve the present academic structure. He has the confidence and respect of both faculty and students.

With regard to the Chilean scientists remaining in the country the following must be said. These people are labouring under very difficult circumstances which are mainly economic. They have very low salaries (which are in line with those of others), mainly because of the difficult economic conditions of the country caused by the previous government; recovery is still very incomplete. For the same reason, funds for research are very limited, and it is very difficult for these people to carry out experiments using modern techniques. Furthermore, subscriptions to journals in libraries are running far behind, also for lack of funds, which makes the situation doubly difficult. Nevertheless, Chilean scientists are trying very hard to maintain a research establishment that is in bad shape although it was flourishing four or five years ago. But there is hope. CONICYT is operating again, fulfilling the purpose for which it was originally created during the Frei administration. Also, the government has rescued the Academy of Sciences from financial disaster. More important is the fact that government authorities are listening and are sympathetic to the plight of the local scientists in terms of improving salaries and making available more funds for research and so on.

Inaccurate letters of the type published in *Nature*, although well meaning, do not help those still in Chile. They create a distorted image of the country that may prevent foreign help which is badly needed in keeping what is left after the debacle of the past three years. Scientists who remain in Chile are not fascists but people sincerely devoted in pursuing their academic careers and training future researchers. In fact, some have received tempting offers from abroad and have refused to leave the country. They are far more courageous than those who left to practice 'gauchisme de salon'. The latter and their supporters should be more accurate in their statements, as one would expect from scientists, since these shot-gun approaches only hinder the struggle of dedicated scientists working in a difficult environment. ●

international news

THE Central Policy Review Staff (CPRS), the Think Tank, surfaced this week to publish a report on Energy Conservation (HMSO, £1). It has already been estimated that Britain should eventually be able to save up to 10% of its forecast energy consumption and the report details how this may be most usefully achieved. With its eyes firmly on the possible, it eschews long term once-and-for-all solutions such as nuclear fusion and the efficient use of solar energy, and concentrates on the small scale short to medium term answers. The electric car is a firm favourite; and better insulation to reduce heat loss, smaller cars, greater use of diesel rather than petrol engines and a reliance on the self-regulating effect of more expensive fuel all figure as feasible ways of conserving our energy over the next 25 years.

The most important conclusion for British research is a negative one, that Britain cannot conceivably follow up fully all the possible answers. The report does, however, pick out some fields in which practical research should be stepped up. For the rest, we should concentrate on monitoring the work of other countries, mainly though not exclusively through the Energy Technology Support Unit at Harwell. One of the favourite topics for further research in Britain is the electric car. For this to be feasible it is assumed that the electricity to recharge the batteries will by then be generated mainly by nuclear power.

Three ways of powering the electric vehicle are considered: hybrid systems

Get cracking and count the kilowatts

comprising a battery and a small internal combustion engine, fuel cells, and electric batteries. Of these, electric batteries are considered to be the most attractive. Further work is certainly justified, the report thinks, on the sodium-sulphur battery, to establish its technical viability and costing.

The only strong contender to replace fossil fuels in electricity generation is nuclear fission. Solar power and nuclear fusion, along with windmills, tidal power and magnetohydrodynamics are dismissed as too long term. But wave power is given the go ahead and the technical and economic appraisal now in progress at the National Physical Laboratory is welcomed.

One major recommendation, which has been increasingly advocated by the architectural profession, is an improvement of insulation standards in new domestic housing, and encouragement of owners of existing housing to bring their insulation up to scratch. The insulation in many British homes would not be acceptable to a modern pig farmer for his pig houses, says the CPRS, and there is therefore great scope for improvement in this direction. The Health and Safety at Work

Bill, now going through Parliament, will in fact enable the insulation standards in new housing to be raised. A massive programme to educate the public is envisaged, and this will probably concentrate on the house owner's pocket.

No policy can hope to reduce energy consumption drastically in the very near future. Any measures that the government do put in hand will be unlikely to show results until after the 1980s, especially as the emphasis of the report is on voluntary and self-regulating measures. No energy police for instance. The report has no revolutionary suggestions, but points out that relatively small individual savings, as a result of, for instance, better insulation, more efficient electricity generating equipment and the use of smaller motor cars, should eventually be able to save the target 10% of energy consumption, provided that they are acted on now as a matter of urgency.

The message from the top is, therefore, that people must be made conscious of the full cost of energy and the opportunities for conservation. This should encourage them to save their own money and is preferred to the strong-arm approach. One idea for industry is that companies should be encouraged to start 'energy auditing' and even publish the results in their annual reports. The psychology of economic self interest and the dislike of public disapproval are obviously considered to be more powerful in the long run than a corps of Energy Inspectors or Temperature Police.

BRITISH Secretary of State for Energy, Eric Varley, has appointed Dr Walter Marshall (left) as Chief Scientist in the Department of Energy. Initial reactions of relief that a key post has been filled after months in caretaker hands have been tempered somewhat by the details of the new man's brief, which says specifically that Dr Marshall shall not hand out any advice on overall nuclear policy or on UK Atomic Energy Authority (UKAEA) matters unless he is specifically requested to do so by the Department of Energy with the prior agreement of the UKAEA.

Since Dr Marshall has been a member of the UKAEA for two years, and

Director of the Atomic Research Establishment at Harwell since 1968, it seems on the face of things that the government is missing the point of the operation by directing his attention to energy issues excluding those which he is uniquely equipped by his experience to judge.

However, the choice of reactor for the next stage of Britain's nuclear programme has probably been made already, and whatever the department may say about Dr. Marshall's brief avoiding 'conflicts of interest', it's highly unlikely that he wasn't among the people consulted by Mr Varley, however informally, before the choice was made.

WHEN President Nixon abolished the Office of Science and Technology last year, thereby ending 15 years of scientific presence in the White House, his action was greeted with a predictable flood of complaints from the scientific community and rumblings of discontent have continued ever since. Now the National Academy of Sciences, the most prestigious scientific body in the United States, has taken to print to deplore the banishment of scientists from the corridors of power and to urge that they be restored through the establishment of a Council for Science and Technology in the White House.

The idea is neither new nor particularly startling, but the fact that it has come from the academy has accorded it considerable attention, particularly on Capitol Hill. The proposal is, essentially, for a three-member council to be established to help in dividing the budgetary pie for science and technology, to provide independent analyses of military research and development programmes and to have a strong input into foreign and domestic science policymaking.

When Nixon scrapped the Office of Science and Technology (OST) by executive fiat in January last year, he also designated Dr H. Guyford Stever, Director of the National Science Foundation, as science adviser—a position previously occupied by the Director of OST. Stever, who is head of one of the smaller scientific agencies in the federal landscape, was, however, given no authority to advise on military research and development—which accounts for more than half of the federal science budget—because “the Department of Defense has strong capabilities for assessing weapons needs”. And he was also told to report to the President through Dr George Shultz, who was then Nixon’s adviser on economic affairs. •

Although Stever has generally been credited with doing a commendable job, given the limit to his powers, the fact that the science advisory apparatus was shifted from the White House to a relatively obscure part of the federal bureaucracy rankled considerably among members of the scientific establishment. And it did not help matters much when Nixon, seeking advice on energy research and development, turned not to Stever but to Dr Dixy Lee Ray, chairman of the Atomic Energy Commission. Since that was perhaps the most important exercise in science policymaking last year, the fact that Stever was seemingly overlooked when the task was assigned suggested that Nixon was not paying much attention to the science policy machinery that he had established.

Central to the complaints that have

Scientists want a foot in the White House

by Colin Norman, Washington

been raised about the new arrangements for science policy is that although Stever may be an able man, and although he has established an office to provide staffwork on policy questions, the fact that he is not in the White House puts him in a weak position to orchestrate the federal government’s scientific activities, which are scattered over numerous different agencies and departments. The White House is the place where interagency disputes are settled, where coordination of programmes takes place and, most important, where final decisions on the Administration’s budget are taken. Thus, the argument goes, for scientific advice to be effective it must come from a White House office.

That, in short, is the reasoning behind the academy’s proposal for a Council for Science and Technology. The proposal, which was released during Congressional hearings last week recommends the following features for the Council for Science and Technology:

- It would consist of at least three people, appointed by the President; it would have a small staff, and it would be able to call upon consultants and panels of outside scientists for advice.
- The council would establish strong links with the three chief policymaking organisations in the White House—the Domestic Council, which provides coordination and policy guidance for a range of domestic programmes, the National Security Council, which does the same for defence matters, and the Office of Management and Budget, which holds the purse strings for all government departments and agencies. The academy suggests that the chairman of the Council for Science and Technology should sit on the Domestic Council, since that body must deal with “a substantial number (of policies and problems) which involve components of science and technology”. Arrangements with the National Security Council would be more informal, but participation by the proposed Council for Science and Technology in defence policymaking would at least rectify one of the major deficiencies in the present science policy system—lack of independent scrutiny of Defense Department programmes. As for the Office of Management and Budget, that body establishes priorities among federal programmes and agencies through the annual budget. Thus, the academy argues, it is essential that it be provided

with strong input from the scientific community in its deliberations over the federal government’s \$20,000 million science budget.

- Finally, the academy recommends that the proposed council should deliver an annual report on major developments in science and technology. In fact, OST did attempt to produce such a report during its last year of life, but the effort was eventually dropped partly because it engendered considerable opposition from some sectors of the government.

Nowhere in its report does the academy say outright that the present system is not working properly—indeed, at one point, the report says that “we view with admiration the efforts of the Director of the National Science Foundation”—but implicit in its argument is that the arrangement just cannot cope with many of the problems with which it has to deal, simply because it is one step removed from the centre of power. But a fundamental question is whether any science advisory apparatus can be made to work in an Administration which has not so far shown much enthusiasm for science advice. The OST arrangement, for example, even though it was at the centre of power, lost considerable influence during the later stages of its life, partly because PSAC made some public recommendations which were diametrically opposed to Administration policy—a prime example being a report opposed to development of the SST which was made public when the Administration was fighting Congress to get approval for the SST programme.

Nevertheless the Academy’s proposals met with a warm reception on Capitol Hill, for last week Senators Frank Moss and Warren Magnuson proposed a bill which would create a Council of Advisers on Science and Technology in the White House. Hearings will be held on the measure on July 11 by the Senate Committee on Aeronautical and Space Sciences and the Senate Committee (which Moss and Magnuson, respectively, chair) and there is a good chance that the Senate will endorse the proposal by the end of the year. But the House of Representatives is unlikely to move that quickly. The Committee on Science and Astronautics is now in the middle of a protracted study of the national science policy machinery, and although the Academy’s recommendations went down well with the committee, it is unlikely that it will be ready to suggest changes in the machinery in time for the House to act this year. But there is every chance that Congress will act next year to reestablish a White House science policy office, in which case no President would be able to get rid of it without congressional approval.

Cooperation in coal research

by John Wilson

BRITAIN and the United States are to share the results of almost all their research into the mining and use of coal. This was decided formally on June 26, when an agreement was signed simultaneously in London by Sir Derek Ezra, Chairman of the National Coal Board (NCB) and in Washington by the Honorable Rogers C. B. Morton, United States Secretary of the Interior. Over the live telephone link from Washington Mr Morton said that it was "not only feasible but imperative" that the two countries exchange information now. For his part, Sir Derek described the agreement as "about the most comprehensive list that could have been laid down". He emphasised, however, that the agreement should not be seen as being exclusive, and mentioned commitments to other countries.

The full text has not yet been released but fifteen major areas of research are specifically named. These are the gasification, hydrogenation and solvent extraction of the coal; long wall mining techniques (needed in deep mines); automatic cutting machine control; coal preparation techniques; automatic measurement of coal characteristics; effluent control; minestone disposal; noise and dust control; safety research in the workings (degasification, subsidence studies, roof supports, and prevention of spontaneous combustion); air pollution control (treatment of flue gases); open cast mining techniques (including restoration of the site); advanced power systems and fluid bed combustion.

How cooperation on many of these topics should best be established is not yet finalised but further discussions are expected to take place at an international meeting on coal research which is to be held in London in October.

The agreement runs initially for three years and is extended automatically for periods of two years unless one of the parties withdraws. Each side must call for the information it wants and there are provisions in the agreement for the safeguard of patents and the exchange of personnel.

With Sir Derek Ezra in London was Dr William Gouse, Director of the United States Office of Coal Research and Development and Acting Director of the Office of Coal Research. Saying that coal "was something that the United States had discovered last fall" he described its importance to the United States as an energy source of its own from which clean fuel could be prepared. But he said that there was a shortage of people with the appropriate research background to exploit

these resources—a weakness in mining technology being the weak link.

As part of President Nixon's drive to make the United States independent of external energy sources by 1980, the Department of the Interior plans to spend about \$3,500 million on mining and coal utilisation research over the next five years. And it hopes that this sum will almost be matched by private industry.

Britain will spend a lot less. In plans which Sir Derek Ezra says have been "well received" by the Secretary of State for Energy, Mr Eric Varley, the NCB is calling for \$100 million (£40 million) to be made available over the same period.

But this disparity in expenditure should not be taken as a measure of each country's contribution to the research agreement. Sir Derek Ezra says that "this agreement will be very much a two-way process. We are not just latching on to a great American effort, we have much to give in return". The NCB's knowledge of the basic processes in coal utilisation methods is sound, he continues, and the United States has the resources to set up the necessary pilot schemes.

The United States is particularly interested in the fluid bed combustion of coal—a technique in which the bed of coal and ash inside a furnace is given the properties of a liquid by the upward passage of air. It hopes to use this method to generate electricity and is spending \$30 million next year on the building of a pilot plant. Under the agreement just signed, the results from this and other similar pilot projects will be available to Britain.

The United States has only recently discovered that it will have to dig deep for its coal. This is not only to obtain sufficient quantities of high grade coal but also to avoid the wrath of the environment lobby which is violently opposed to strip mining.

Noting that Britain has by far the biggest mining industry in Western Europe, Sir Derek suggests that the NCB can assist the United States with the long-wall mining technique that it must now use—perhaps by the export of specialised mining equipment. The NCB also has considerable experience of the health problems posed by noise and dust in deep mines (indeed over the past four years Britain has allocated £4.5 million to medical and engineering research connected with dust control and pneumoconiosis) so there are many areas of both mining and coal utilisation research where Britain's expertise will benefit "Project Independence". But perhaps the most important aspect of the new agreement is that it will allow ideas generated on either side of the Atlantic to be shared between both parties.

Copper exploration proposed for Exmoor

by Roger Woodham

BRITISH Kynoch Metals Ltd. has applied for planning permission to explore for copper on the borders of the Exmoor National Park in Devon. The company, jointly owned by Imperial Metal Industries and British Insulated Callender's Cables, is thinking in terms of scout drilling of ten holes less than 350 feet deep to start with, but would ultimately seek permission to re-establish a mining operation in the area if things turn out well.

The first thing to be said is that open-cast mining is out of the question because of the nature of the mineralisation. The metal ores in the region are in lensoid bodies that are relatively narrow and lie *en echelon*. There is not the large extent of relatively poor grade ore (less than 1%) that makes open-cast mining attractive.

British Kynoch is hoping to prospect on "a few square miles" of the Stucley estate at Heasley Mill in the North Molton area of Devon. This part of the estate includes several old workings, in particular the Bamfylde Mine which was used intermittently between the early eighteenth century and 1884. Its output was never very great by today's standards, however—between 1860 and 1881 it produced 5,000 tons of copper ore, the grade of which may have been 17% or so locally but was probably more like 5-7% overall. The mine goes down 900 feet and the main vein is some 2,000 feet long.

Mr P. F. A. Loffler, Managing Director of British Kynoch, said last week that geochemical and geophysical surveys had provided "some encouragement". These methods are, however, no substitute for drilling and examining a core because copper can find its way into the soil from artificial sources and the detection by geophysical methods of conducting material at depth may indicate no more than the presence of iron ore or graphite, hardly a prize for any mining concern.

Mr Loffler said that as the area is well wooded and made up of valleys and combs, the operations could easily be screened. His company has declared that the "visual impact of equipment, plant and offices would be minimal" in the event that mining was started again and that no local smelting is contemplated.

Local reaction is hard to gauge at present because nobody has had time to investigate fully the implications of the planning application. There is, however, general relief that open-cast operations are not being considered for the site.

THE unofficial Moscow seminar on "Collective Phenomena and the applications of physics to other fields of science", scheduled for July 1-5, 1974 now must pass into history as "the seminar that never was". With the arrest on Friday June 28 of Sinologist Vitali Rubin, it would seem that all leading members of the organising committee were in custody at the time of going to press. According to a cousin of Professor Mark Azbel, the arrested organisers are held outside Moscow, in detention centres which have previously been used for the temporary removal of dissidents from circulation. The centres mentioned are at Volokolansk and Serpukhov—the second showing a certain irony on the part of the authorities. Those intending participants not in custody are under virtual house arrest with police cars parked outside.

Seminar that never was

On hearing of the arrests, Professor Edward Stern, one of the three international secretaries of the seminar, began an intensive campaign in Washington to effect the scientists' release. A delegation from the intending participants met Senators Jackson, Javits and Ribicoff, who undertook to send a telegram to Dr Kissinger, asking for their release. They also met Senator Hartke of Indiana who claims to be on good terms with Brezhnev, and who promises to intercede personally on their behalf. Acting Secretary of State Sisco also showed considerable interest in the plight of the scientists, and undertook to bring it to Dr Kissinger's

attention. Eleven Nobel Laureates endorsed the principle, which has been conveyed to Mr Nixon in Moscow, that the right of scientists to emigrate without harassment should be written into any bilateral agreement between the United States and USSR.

Meanwhile, it has been learned that Mrs Nina Voronel was informed on Saturday June 29 that the group will be released after the scheduled seminar dates have safely passed. What their subsequent fate will be remains uncertain. One of them, Corresponding-Academician Venyamin Levich, has, however, now been granted permission to emigrate "at the end of 1975", while his sons Venyamin and Aleksandr can leave at the end of this year. If this is an omen of events to come, the ill-fated Seminar will not have been convened in vain.

It is ten years since the June 1964 elections to the Soviet Academy of Sciences which marked the beginning of the end of Lysenkoism and the re-introduction of Mendelian genetics in the Soviet Union. Although the Russians are usually eager to mark any significant anniversary, this particular one is not liable to receive the usual acclamation of celebratory meetings and publications. Nevertheless, a recent decree of the Central Committee of the Communist Party of the USSR and the Council of Ministers of the USSR does, in oblique fashion, form a kind of epitaph to the Lysenko period, by indicating the harm done to the development of Soviet science by almost a quarter of a century of opting out of world trends in research in genetics and molecular biology.

The Decree, published on May 21, 1974, deals with "the question of measures to accelerate the development of molecular biology and molecular genetics and to use their achievements in the national economy". It begins with the face-saving observation that "in recent years, on the basis of the wide use in biology of the achievements of chemistry, physics and mathematics, it has become possible to investigate the molecular mechanisms of the most important processes determining the existence and development of living matter". (This would logically imply that the earlier decision, in 1948, to stop all genetic research and, on the orders of the MGB—now the KGB—to destroy all *Drosophila* held in laboratories by drowning them in boiling water, was quite 'correct'; the necessary achievements in other fields had not yet been reached.)

Now, however, "fundamental discoveries in this branch of the natural sciences" have been made (it is not said by whom), which "have great

Epitaph to Lysenkoism

from Vera Rich

theoretical and practical significance for the development of agriculture, medicine and a number of branches of industry". Nevertheless, it is found that "the general level and scale of research on molecular biology and molecular genetics in our country is still insufficient. There are only a few highly qualified specialists making ready in this field. There are serious deficiencies in the organisation of the production of special scientific instruments and high class apparatus, the necessary range of chemical reagents, materials and biological preparations."

Accordingly, since "the Central Committee of the Communist Party of the Soviet Union and the Council of Ministers of the USSR consider that the achievement in the shortest possible time of the foremost level of development of molecular biology, molecular genetics and other branches of natural science immediately connected with the study of the physico-chemical principles of life phenomena" constitutes "one of the most important problems of Soviet science at the present time", the appropriate steps are to be taken. The Academy of Sciences, the State Committee for Science and Technology, the State Planning Committee and the various ministries and departments are charged with "ensuring the necessary rate of development of these sciences and a wide use of their achievements in agriculture, medicine and industry", with "strengthening the basic trends of fundamental research", and also with drawing up a concrete programme of research and design for 1974-80.

This last clause is extremely signi-

ficant—the new policy becomes effective immediately, without waiting, as would normally be expected, for the beginning of the next five-year plan in 1976. Since the logistics of implementing such mid-plan changes of policy in the framework of the rigid quinquennial budgeting of financial and manpower resources are considerable, it seems clear that what is involved is not only a change of planning policy, which could have waited another 18 months, but something close to panic measures.

The practical details contained in the Decree are sparse, as always. We learn, however, that a special Inter-departmental Scientific and Technical Council has been formed to coordinate research in this field, that means have been assured for the training of specialists, scientists and instructors, that new scientific research establishments and training colleges are to be opened and existing ones expanded, and also that "research bases" are to be constructed. The production of the required instruments, reagents and other necessities is to be "considerably expanded".

The Decree ends with the conventional expression of the confidence of the Central Committee and Council of Ministers that all persons and organisations concerned will carry out their appointed tasks in this new expansion of Soviet science in the fields of molecular biology and molecular genetics. In this atmosphere of all shoulders to the wheel, it seems unfortunate, for the Soviet authorities, that they can no longer call on the help and assistance of the chronicler of the Lysenkoist "pseudoscience", who did so much towards its overthrow—Zhores A. Medvedev, who, a year ago, they saw fit to deprive of his passport.

In India the explosion is seen very differently

from Narender K. Sehgal, Jullundur

The news on May 18 of India's nuclear explosion sent a wave of elation through the country. People were simply thrilled, despite the difficult economic situation. Even Indians abroad could not remain unaffected by the event. The President of the Indian Students' Association at the University of Illinois in Chicago wrote in a letter to a New Delhi daily newspaper: "... If anything, the reaction of the average American has been one of incredulity as to how such a country could pull off something like this. ... The Indian community by and large welcomed the blast as a veritable success for Indian scientists and engineers". Back home, to show their appreciation, the Federation of Jullundur Engineering Associations passed a resolution announcing a token cash award of Rs2100 for Shri H.N. Sethna, Chairman of the Atomic Energy Commission (AEC), for "successful explosion of a nuclear device".

The Indian scientific community, like other sections of the population, hailed the underground nuclear experiment as an important development in the country's atomic energy programme, signalling attainment of a certain degree of sophistication in nuclear technology. Dr S. M. Sircar, Director of the Bose Institute in Calcutta, said that the Atomic Energy Commission had done a good job. Dr D. Bose, Director of the Indian Association for Cultivation of Science, said it was a good step forward in making use of atomic energy for purposes other than war. Dr S. P. Ghosh, Head of the Department of Nuclear Chemistry at Patna University in Bihar, said India's success in the field of nuclear technology represented peaceful research activities for geological exploration. He added that in the peaceful use of nuclear energy there was also a possibility of constructing atomic weapons and this explosion shows that "Indian technologists are capable of doing so."

Following the explosion, atomic energy in general and the country's programme in this area in particular became hot topics for discussions, talks and seminars. Dr H. S. Hans, Head of the Department of Physics at the Panjab University in Chandigarh, hailed the nuclear experiment in a radio talk from Jullundur and explained various aspects of India's atomic energy programme. Speaking on "Nuclear Explosion" at the India International Centre in New Delhi Dr B. K. Nayar, Executive Secretary of the Indian National Science Academy,

said the success achieved by India in the nuclear explosion must be a matter of both envy and dismay to many. He felt that so far as application of nuclear energy for peaceful purposes in India was concerned, a better experiment might not be easily envisaged. He stressed that a crater-forming explosion could be utilised successfully in creating channels, dams and storage for underground gases and radioactive materials released by nuclear tests.

Reactions to the explosion from abroad have been on expected lines. The Chairman of the French Atomic Energy Commission has congratulated his Indian counterpart. According to scientists, India had merely staged a neat and skilful demonstration of what she had been believed capable of for some time. Even so, there has been criticism from some foreign quarters, mostly in the form of unofficial press comments.

Although there is undoubtedly an understanding here about stands taken by non-nuclear countries, protestations from those possessing stockpiles of nuclear weapons have failed to impress anyone. Doubts have been cast on India's peaceful intentions in regard to the explosion, pointing out rather irrelevantly that even Russia and the United States have had little success in using nuclear explosions for peaceful purposes. Maybe India will be able to show the way.

By and large scientists here seem satisfied with the countrywide favourable response evoked by the nuclear experiment. There is concern, however, especially among those connected in any way with the atomic energy programme, at the patently false impression (created by press and other comments from abroad) that the entire Indian effort in the field of atomic energy had been directed to-

Shot in the arm

ward detonating a nuclear device. Nothing could be further from the truth. India's atomic energy programme comprises activities ranging over a wide variety of fields: radio isotopes, medicine, food and agriculture, electronics, lasers, minerals, metallurgy and so on—and of course power generation, which has been one of AEC's major concerns.

In a television interview on May 31, of the AEC, the Chairman, Shri Sethna, pointed out that the commission was spending seven times more on nuclear research in agriculture, medicine and cancer studies than what was spent on conducting the test which, according to him, cost the AEC Rs 30 lakhs (lakh = 100,000).

To Indian science the explosion has come as a timely shot in the arm. This modest achievement (and perhaps others that may follow) could provide just the fillip needed to bring Indian science and technology into their own.

Indian scientists feel that India's mastery over nuclear explosion technology for peaceful purposes is bound to result in important advantages: India's nuclear neighbour will feel appropriately restrained and chances of confrontation between the two will diminish; Indian views on disarmament, particularly with respect to nuclear weapons, will carry a lot more weight now; the idea and concept behind the nuclear Non-Proliferation Treaty will have to undergo adequate changes to make it more just for the non-nuclear-weapon countries; and India may now be in a far better position to press for initiation of discussion on dismantling of all existing nuclear weapons and on a worldwide ban on all types of nuclear activity for war purposes.

"THE choice before mankind is a very simple one: nuclear disarmament or oblivion. In the absence of disarmament, more and more nuclear weapon powers will emerge. A limited nuclear war will eventually break out which may well escalate to a strategic nuclear exchange between the superpowers and extinguish our civilisation. The nuclear paradox is Man's total inability to cope with the obvious, even when it is a matter of life and death for the human race." With these words Dr Frank Barnaby, Director of the Stockholm International Peace Research Institute (SIPRI), justified the pessimistic outlook of the Institute's *Yearbook 1974* recently published in Stockholm. Like its four predecessors, this yearbook is about armaments and disarmament. After surveying the state of the armed world and the developments affecting it during 1973, the institute restates its commitment to general and complete disarmament as the only possibility for survival.

SIPRI readers have by now learned to expect the authoritative and sobering picture which emerges from this yearbook as from the institute's many other publications. It comes as no surprise to read that "... by the end of 1973 there was still little evidence that the degree of disorder in international affairs was decreasing". The bright spots of the year fall into place as acts of political necessity which have done nothing to stop the proliferation of conventional weapons or the continuing pressures towards technological refinement of both conventional and nuclear arms.

In 1973 the world spent \$207,000 million on arms, of which \$20,000 million was for military research and development. Since 1968 world military expenditure has been constant at about this level; therefore the latest figure represents a slightly lower proportion of world GNP now than it did then.

SIPRI pulls it all together

The unchanged figure however, disguises a disturbing trend: "The share of world military expenditure absorbed by the United States, the Soviet Union, France and the United Kingdom, taken together, has declined from 82% in 1955 to 70% in 1973. This does not reflect a reduction in the military capability of these four countries but rather indicates the magnitude of the increase in militarisation elsewhere." India's recent nuclear explosion illustrates this only too well.

The peculiar value of the SIPRI year books is that they relate all the happenings of a year, putting the events hailed as political milestones in perspective beside continuing world trends. Amidst the triumphant conclusion of the Israeli-Syrian disengagement agreement and the optimistic forecasts of its effect on future oil deliveries, for example, it is easy to overlook what is happening in other parts of the Middle East. The Persian Gulf is a critically important area for the shipment of oil. In recent years, the countries bordering the Gulf have, according to the yearbook, dramatically increased their military expenditures. Iran and Saudi Arabia have led the way. Over the decade 1963-1973 the average annual rate of increase of military expenditure in these countries was 23%. During 1973, Iran had outstanding orders for about 800 Chieftain main battle tanks, 250 Scorpion light tanks, more than 200 F-4E/F-5E fighter aircraft and nearly 500 helicopters, including about 200 Sea Cobra gunships armed with the latest US anti-tank missiles. The prospect of the Gulf countries being armed to the teeth and about to wield such influence

over oil shipments may well make us rethink the current relief over developments in another part of the Middle East.

Current nuclear events make the yearbook's discussion of nuclear policies particularly interesting. The statement on January 10 by the United States Secretary of Defense that the United States would in future pursue a counterforce strategy is interpreted by SIPRI as a justification for continuing the development of weapons for whose future deployment the doctrine of 'mutual assured destruction' provided no rationale. Of particular concern is the fact that enormous resources are being devoted to antisubmarine warfare technology, which is already sufficiently advanced to allow the destruction of a portion of the enemy's strategic nuclear submarine force. On the tactical level, it has been suggested that accurately delivered low yield nuclear weapons should replace the higher yield nuclear weapons now deployed, particularly in Europe. SIPRI objects to this proposal because "it is of paramount importance that an absolute 'firebreak' should be maintained between nuclear and conventional war".

It is surprising that SIPRI emphasises its basic commitment to effective disarmament as the only sure way of lessening threats all over the world, in spite of the facts that the yearbook is aimed largely at governments and that the institute is well aware that 'disarmament' is a dirty word in many government circles. The official intolerance of disarmament detracts from the practical value of the Yearbook's solution, for history shows that political will is essential for negotiated progress in any direction. In going against the stream, SIPRI is not merely being politically naive. It is attesting to the fact that it sees no middle way between disarmament and annihilation.

THE US House of Representatives voted last week to kill the Large Space Telescope (LST)—one of the most important astronomy programmes being planned for the 1980s—by deleting funding for the project from NASA's budget. If the Senate follows suit, NASA will have to revamp the project and come up with a cheaper option, but according to congressional sources, it is likely that the Senate Appropriations Committee will restore at least some of the money to keep LST alive.

NASA had asked for some \$6.2 million for the 1974-75 fiscal year for planning and design of the LST, before moving into the development phase. But the Appropriations Committee recommended that the money should

LST in danger

be denied this year and that "A less expensive and less ambitious project be considered as an alternative." The recommendation was approved by the House itself last week when it voted on NASA's budget.

A 120-inch optical telescope, the LST would be about 100 times more powerful than the largest ground-based instruments now in operation. It would be launched in the early 1980s—probably in 1981—by the space shuttle and it would be periodically serviced and upgraded during its 15-year lifetime. It has been enthusiastically endorsed by the Space Science Board of the

National Academy of Sciences but the House Appropriations Committee was evidently concerned at the large estimated costs of the project—between \$200 and 300 million.

Now that it has been approved by the House, NASA's budget must be considered by the Senate. The Senate Appropriations Committee is likely to report out a bill later this month and if the full Senate does eventually restore funding for the LST, the matter would have to be resolved by a House-Senate conference committee. Congressional sources predicted that the funds would be approved by the Senate and agreed to by the conference committee, but the outcome at this stage is far from certain.

news and views

Single mutation with two effects in tRNA

SINCE suppression was first discovered by the isolation of mutations that allowed some transfer RNAs to respond to nonsense codons instead of to their usual nucleotide triplets, the effects which mutational alteration may have upon tRNA have proved to be one of the most useful probes for investigating its function. The classical suppression of ochre (UAA) and amber (UAG) nonsense codons proved to be due to substitutions in the anticodons of tRNAs for glutamine, leucine or tyrosine, all possessing codons related to the nonsense triplets by a single base change. Missense suppression can result from a similar phenomenon, when a tRNA suffers a change in its anticodon which causes it to recognise a codon that usually represents some other amino acid. Another form of suppression involves frameshift mutations, in which a mutant tRNA restores the correct reading frame of the message, apparently acting at the codons GGG or CCC; whereas tRNA for glycine, for example, usually recognises GGG, a mutant seems able to respond to GGGG.

All these mutations are dominant; the presence of mutant tRNA achieves suppression. But what happens in the haploid bacterium at codons to which the mutant tRNAs would formerly have responded? When dominant suppressors can be isolated, presumably more than one tRNA must recognise their wild type codons, so that the capacity to translate these triplets remains even after mutation of one of the tRNAs. This explains why only some of the amino acids possessing codons related by single changes to the nonsense triplets can generate suppressors—presumably the others are recognised by only a single, essential tRNA whose mutation is lethal.

But the objection to mutation in essential tRNAs is overcome if the cell is made diploid for these genes: as Soll and Berg (*Proc. natn. Acad. Sci. U.S.A.*, **63**, 392; 1969; *Nature*, **223**, 1340; 1969) showed, in this case further suppressors can be isolated and they are recessive-lethals—if the bacterium is returned to a haploid condition, the suppressor tRNA is lethal, because there is no tRNA able to respond to its former codons. One of the two recessive-lethal suppressors that they isolated, *su7⁺*, has the surprising property of inserting glutamine at amber codons, surprising because dominant glutamine suppressors have previously been isolated and recessive-lethals were expected to implicate new amino acids in suppression. The unusual properties of the glutamine lethal-recessive suppressor are the subject of studies reported in the *Journal of Molecular Biology* by Soll (**86**, 233; 1974) and Yaniv, Folk, Berg and Soll (*ibid.*, 245).

Until very recently, all suppression—nonsense, missense or frameshift—mediated by tRNA seemed to be due to changes in the sequence of the anticodon that change the coding response of the transfer molecule. But Hirsh (*J. molec. Biol.*, **58**, 439; 1971) found that a UGA suppressor results from a mutation at position 24 of tryptophan tRNA, not located in the anticodon but allowing the molecule to respond to UGA as well as to its usual codon, UGG. And mutations affecting not the codons recognised by tRNA but instead the amino acid with which it is charged were recently isolated by Smith and Celis (*Nature new Biol.*, **243**,

66; 1973) and Celis *et al.* (*Nature new Biol.*, **244**, 261; 1973; see also *Nature*, **249**, 690; 1974). By examining the ability of cells possessing the *su3⁺* gene, which inserts tyrosine at amber codons, to suppress nonsense mutations at which tyrosine is not acceptable, they isolated mutants of *su3⁺* which continue to recognise the UAG amber codon, but insert glutamine instead of tyrosine. All five mutations constituted single base substitutions in the amino acid acceptor arm of the tRNA.

That the insertion of glutamine by the *su7⁺* suppressors results not from mutation of a glutamine tRNA but instead from a change in the charging specificity of another tRNA is the conclusion supported by the studies of Soll and Yaniv *et al.* Soll reports that the *su7* locus in *Escherichia coli* is identical to a locus in *Salmonella typhimurium* at which Miller and Roth (*J. molec. Biol.*, **59**, 63; 1971) previously isolated recessive-lethal suppressors of UAG and UGA codons that seem to be allelic. By obtaining a $\phi 80$ phage carrying the *su7⁻* gene, Soll showed that the *E. coli* locus also can suffer single step mutations to yield *su7⁺*_{UAG} or *su7⁺*_{UGA} suppressors. That both suppressors result from mutation of a single tRNA gene carried on the phage is suggested by the subsequent conversions possible from the

Is Jupiter lord of the Solar System?

THE idea that Jupiter and the Sun might be considered more sensibly as a binary system than in the respective roles of humble planet and dominating star is not particularly new. But on page 35 of this issue of *Nature*, Drobyshevski takes the idea an intriguing step further; according to his calculations, the dominant partner in the early stage of the development of the binary was Jupiter, and not the Sun.

Jupiter is certainly more like a small starlike body which has insufficient mass to trigger nuclear burning than like the other planets of the Solar System. According to Drobyshevski, one can be more specific and identify Jupiter with the core of the protosun. The process by which the original primary in the evolving binary system has become very much the secondary will be familiar to students of stellar evolution. At one time, it was something of a puzzle that the lower mass components in many binary star systems are found to be more highly evolved than their more massive companions, since a more massive star should evolve more rapidly. But this has now been explained in terms of mass exchange between the components of binary systems.

That is essentially how Drobyshevski explains the evolution of the early Solar System, with details of the process also offering a reasonable explanation of the formation of the other planets. And as a final bonus, the slow rotation of the Sun also emerges from the calculations when the angular momentum of the material streaming between the original binary companions is considered.

JOHN GRIBBIN

$su7^{+}_{UAG}$ and $su7^{+}_{UGA}$ alleles. The $su7^{+}_{UAG}$ tRNA can be mutated to yield an ochre suppressor recognising UAA and UAG. The $su7^{+}_{UGA}$ tRNA can be mutated to yield a UAG suppressor, although this results in loss of UGA suppression. These conversions can all be explained by single base mutations if the $su7^{-}$ tRNA represents the single species in the cell coding for tryptophan that responds to UGG. This can generate a UGA suppressor by mutation at position 24 in the dihydrouridine loop; and a change in the anticodon would generate a recessive-lethal UAG suppressor. Except for the initial generation of $su7^{+}_{UGA}$ from $su7^{-}$ tRNA^{Trp}_{UGG}, all the conversions observed can be achieved by single changes in the anticodon.

Sequencing studies confirmed that the amber and ochre $su7^{+}$ suppressors are derived by single base changes in the anticodon of the tryptophan tRNA. Yaniv *et al.* found that a change from CCA in the wild type anticodon to CUA in the mutant $su7^{+}_{UAG}$ is the sole difference between the transfer RNAs. The $su7^{+}_{UAA/G}$ suppressor generated by mutation of $su7^{+}_{UAG}$ represents a further single base substitution, having an anticodon of UUA. But although derived from tryptophan tRNA, the $su7^{+}_{UAG}$ and $su7^{+}_{UAA/G}$ suppressors both insert glutamine at the nonsense triplets to which they respond. This means that the mutation from C to U at the middle position of the anticodon must have two effects: it changes the coding response so that the tRNA recognises UAG instead of UGG; and it alters the charging specificity so that the transfer molecule is recognised by glutamine-tRNA synthetase instead of tryptophan-tRNA synthetase. The second C to U change, generating the ochre $su7$ suppressor, must change the coding specificity to allow recognition of UAA as well as UAG, but leaves unimpaired the new ability of the molecule to be charged with glutamine instead of tryptophan.

Comparing the sequences of the two glutamine tRNAs (which recognise CAG and CAA and differ in seven nucleotides) with the $su3^{+}$ tyrosine suppressor shows few similarities. All five of these mutations are located in the amino acid acceptor stem of the molecule. Four disrupt one of the first two base pairs, and may therefore be effective because they induce a conformation change; the other replaces an adenine not involved in base pairing with a guanine, and presumably this base must be recognised directly, or must influence the conformation of the molecule by an interaction with some other region in the tertiary structure. Each individual mutation may establish some similarity with glutamine tRNA and Inokuchi, Celis and Smith (*J. molec. Biol.*, **85**, 187; 1974) recently showed by constructing a double mutant that two together may enhance charging with

glutamine compared with the single mutants.

In view of the implication of the amino acid acceptor stem as a site for recognition by gln-tRNA synthetase, it may perhaps be significant that the only similarities between glutamine tRNA and $su7$ tryptophan tRNA lie in the base pairs of this region and of the anticodon stem, although of course recent research has pointed to the conclusion that base pairs as such, not their individual bases, may be important in recognition of tRNA. It is not at all obvious why a single change in the $su7^{-}$ tRNA anticodon allows the molecule to be recognised by gln-tRNA synthetase. Perhaps the isolation of further mutants, and determination of the relative extents to which each substitution allows false recognition of tRNA, may allow some definition of how synthetases recognise transfer molecules; but at present this remains unclear.

BENJAMIN LEWIN

Saiga finds safety in numbers

from D. Michael Stoddart

THE story of the saiga (*Saiga tatarica*) is one which could easily have had an unhappy ending. Intense piratical hunting and severe 'djuts' (glazed snow coverings of great persistence) brought the world's total of this antelope during the first quarter of this century to just a few hundred. In the 1930s the game authorities in the Soviet Union totally prohibited hunting and took steps to reduce the herds of nomadic cattle that overgrazed the saiga's range. Nature lent a kindly hand by offering a few winters of relative mildness without serious djuts. By 1954 there were 1 million head of saiga and in 1973 more than 2 million in the Soviet Union. Cropping started in 1955 and during the next 17 years nearly 3 million head were harvested and these produced 58,000 tons of meat. Current studies in Kazakhstan and other areas in which saiga overwinter are being made to find ways of lessening the impact of serious djuts.

An important feature of the ecology of the saiga is the high reproductive

The saiga antelope, chosen as the emblem of the First International Theriological Congress and depicted on one of a special set of postage stamps issued to mark the event.

rate. Old females regularly give birth to twins, sometimes triplets, and young females breed first at 7 months. The rate of embryo resorption is low but noticeably higher after winters with severe djuts when the crust of glazed snow diminishes available food and the animals enter spring in an emaciated state. In concluding his remarks to the First International Theriological Congress held in Moscow from June 6–12, A. A. Sludsky drew attention to the importance of this natural resource to the more isolated regions of the Soviet Union where rail and road transportation links are poor.

A less rosy outlook was presented by I. I. Barabash-Nikiforov and L. V. Shaposhnikov for the Russian desman (*Desmana moschata*), a large, aquatic shrew-like mammal. Like its Pyrenean cousin, the desman is a Tertiary relict. Everywhere it is becoming much less abundant. Today it is to be found only on parts of the River Ob' in West Siberia. Various reasons are thought to have brought the desman to the brink of extinction. Foremost among these is the use by fishermen of creels and trap nets in which many desmans drown. The draining programme of flood plains and the building of levées, the destruction by cattle of riverside vegetation and the interspecific competition with muskrats for bank space are other influential factors. It seems as if the economic and human factors will prevail and even spread to the few safe desman pockets where the creatures can find safe harbourage. Unless special reserves, like the Kljazma Reserve which was abandoned in 1951, are created and recreated soon, the desman will fast become another species only to be found in zoos.

An experimental farm for moose (*Alces alces*) at Kostroma, some 200 miles north-east of Moscow, is leading the way to a new line of domestic meat-bearing species. Bottle feeding of moose calves, group rearing and feeding are giving promising results. Moose cows breed in captivity when they are 16 months old. Their calves grow at a rate of about 300 g per day. On the farm they keep up this rate throughout the year, though wild calves do not usually increase in weight at all during the winter. E. M. Dzshurovich and A. P. Mikhailov are confident that a significant new branch of livestock hus-

bandry is just around the corner.

The congress was not concerned solely with mammals from the Soviet Union, nor just with ecology and production biology. About 1,000 zoologists from many countries of the world took part in a range of seminars and symposia which covered topics such as zoogeography, evolution and taxonomy, endocrinology and gestation, growth physiology, ethology, orientation and signalling, and the problems to be overcome in conserving bears and marine mammals. The USSR Academy of Science (see *Nature*, **249**, 502; 1974) organised the meeting in its 250th anniversary year. The congress has significantly fostered a closer spirit of interaction and cooperation between Soviet and Western zoologists than has hitherto been the case.

Antibody manipulation by malaria parasite

from F. E. G. Cox
Parasitology Correspondent

WITH more than one thousand million potential malaria victims in the world it is not surprising that considerable attention has been paid to possible methods of vaccination against this disease. All the attempts so far, however, have been relatively unsuccessful. All have involved killing or attenuating malaria parasites and using large amounts of antigen. Even then, the results have been variable and protection has been limited. Many workers believe that vaccination against malaria is not possible because of the existence of antigenic variation and cell mediated responses as yet unrecognised. In fact, much of the basic information necessary for the development of a vaccine is already available and it may well be that investigations of antigenic variation and cell mediated responses are irrelevant to immunity to clinical malaria.

Immunity to malaria can be explained in terms of an antibody directed against the merozoites while they are outside the red blood cells. The evidence for this comes from three sources. First, *in vitro* experiments carried out by Cohen and his colleagues at Guy's Hospital Medical School have demonstrated that parasites within their red cells take up ³H-leucine in the presence of immune sera as well as they do in normal sera (*Trans. R. Soc. trop. Med. Hyg.*, **65**, 125; 1971) but that in immune sera the invasion of fresh blood cells is inhibited. They have also shown that merozoites bind to suitable cells (*Nature*, **244**, 40; 1973) and the prevention of this binding by immune

sera could form the basis of immunity. Second, Jerusalem, Weiss and Poels, in a paper that has not received the attention it deserves (*J. Immunol.*, **107**, 260; 1971), showed that fluorescein-labelled antiserum injected intravenously into mice bound only to merozoites and not to intracellular parasites. Third, nobody has observed any damage or signs of changes in parasites within their cells during the immune response.

If it is only the merozoites that are important in immunity, why is it that the antibodies associated with antigenic variation agglutinate infected cells? Part of the answer to this question comes from the work of Brown (*Nature*, **242**, 49; 1973) and Brown and Hills (*Trans. R. Soc. trop. Med. Hyg.*, **68**, 139; 1974). They have found that in *Plasmodium knowlesi* infections in monkeys, infected cells are agglutinated by a non-protective antibody that is easily separated from an opsonising antibody associated with protection. Brown postulates that the agglutinating antibody serves to trigger a switch in antigens and this change allows the parasites to survive in what should have been an immune host. In other words this antibody has been manipulated by the parasite for its own ends. The opsonising antibody is important in protection and is effective against all antigenic variants and the relative rates of synthesis of these two antibodies determine the outcome of the infection.

The protective immune response to malaria is weak and largely ineffective and it is unlikely that any vaccine could produce a better immunity than the natural one. Nevertheless, acquired immunity to malaria does occur and children who survive the first few years of their lives in malarious areas tend to be immune to clinical malaria if not to the infection itself. A vaccine that could be used to see children through their first few years would be invaluable. There is no evidence to suggest that cell mediated responses are important in immunity to malaria so the induction of an antibody against merozoites could well be effective. Possibly all that is required is the antigen involved in binding merozoites to their host cells. As antigenic variation involves an antibody that has nothing to do with protection it is unlikely that antigenic variation would interfere with any protection produced as a result of vaccination against merozoites.

Correction

In the News and Views article "Biogenesis of surface membranes" (*Nature*, **249**, 414; 1974), Dr G. Kreibich's name was misspelled in the penultimate and last paragraphs.

Anthill and tiger counting in the Soviet Union

from Vera Rich

JUDGING from the numerous Soviet press and agency reports, one of the major tasks of Soviet ecologists and conservationists is the taking of censuses of various species of wild life. This applies not only to those species threatened by extinction, but of any that are or might prove of value to the economy. Thus the 1972 census of anthills in Estonia was undertaken, not because the Estonian ant was in imminent danger of disappearing, but because it had been found that an optimum of 3-6 anthills per hectare in stands of timber checks the multiplication of various forest pests. Similarly, the census currently being taken of sables in the Amur taiga will be used for improving the system of distributing hunting licences. Even in the case of threatened species, practical advantages are remembered: the Black Sea dolphin census (1971), which revealed that the dolphin population had doubled since the ban on hunting was introduced in 1965, evoked the remark from its director, A. Chepurnov, at a press conference: "The time is not far distant when dolphins will be used to drive fish into nets, to carry out marine rescue operations and to communicate with underwater laboratories".

The census-taking methods vary considerably in complexity. Counting anthills is a relatively simple task, which could conveniently be delegated to students as part of their practical work, but the estimation of most species is much more difficult. The latest (1973) Black Sea dolphin census, which gave a total of 800,000 (three times the 1965 figure), required aircraft and seagoing ships and took 3 months to complete. The grandiose estimation of the total dry-land flora of the world, carried out by the Botanical Institute of the Academy of Sciences of the USSR, giving a total 2,625,000 M tonne of phytomass, presumably involved satellite data. Sometimes a quantitative result seems impossible to obtain. In the case of the jeiran (a variety of antelope) of southern Tadzhikistan, although "large herds" are now reported where, before protection, only a few isolated specimens were observed, no figures, either absolute or relative, seem to have been established. Presumably, so far, no reliable method of counting them has been devised.

The same difficulty, it might be thought, would arise in the census of Amur tigers made from 1971-73 in the Primor'e region of the Soviet Far East, but an ingenious solution was found—

the investigators counted the tracks of tigers in the snow. Although at first glance this proposal seems to contain a source of confusion in the possible crossing and recrossing of its tracks by the same tiger, the photographs published (*Priroda*, No. 12, 82-88; 1973), show that although snow is not the ideal medium for revealing the fine details of the pad with fingerprint clarify, nevertheless, in practice, little or no confusion arises. Not only did this census give a total of some 110-120 tigers in the area (the figure for the 1940s was 30-40), but it revealed a number of significant details about the habits of tigers in the region.

Now that the Primor'e is being increasingly opened up for forestry, and the like, the tigers seem to be entering into a cautious symbiosis with man. (The Amur tiger is not a man-hunter; on the contrary, it is easily scared off by shouting and arm-waving.) The tigers make use of forest roads used for hauling timber, and seem to have no fear of tractors and automobiles. They appear, and may even hunt, relatively close to settlements and motor roads, and observe human activity from a distance of several metres. If disturbed after hunting, they will drop their prey, but are ready to return to it, even if it has been touched by human hand. And, since the presence of tigers causes a rapid disappearance of wolves from the area, the opening up of the Primor'e is in no way hampered by the protection of the tigers—indeed, their presence may prove an advantage. Providing, therefore, that no illegal tiger shoots take place—a condition which, it is admitted, is hard to guarantee—there seems no reason in principle why the tigers should not continue to flourish in these new conditions of coexistence.

Membrane proteins and serum lipoprotein

from a Correspondent

UNTIL recently, discussions of membrane structure centred around the concept of the unit membrane. The model envisaged was a lipid bilayer with hydrophilic proteins restricted to the outer surfaces where they were attached by electrostatic, non-covalent forces. Although this model was useful for explaining the similarities in physical and chemical properties between artificial lipid bilayers and natural membranes, it failed to account for all the proteins known to be associated with the membrane. This led several workers, notably Singer and Nicolson (*Science*, **175**, 720; 1972), to postulate that globular proteins penetrate into or through the lipid bilayer. This idea has been widely accepted as

a sound working hypothesis, but the mode and distribution of the proteins in the plane of the membrane are still controversial. It has been convenient to divide membrane proteins into two groups; extrinsic proteins remain largely on the aqueous side of the membrane attached by electrostatic forces which can be disrupted by dilute salt solutions whereas intrinsic proteins make substantial contact with the hydrocarbon region of the lipid bilayer and can only be disrupted by use of ionic detergents. In practice, however, this distinction is difficult to apply to any protein because of the lack of structural information.

The human erythrocyte has occupied a central position in membrane research due to the ease of obtaining large quantities of membrane ghosts free of haemoglobin. By SDS gel electrophoresis, more than 20 membrane protein bands have been resolved (see, for example, Fairbanks *et al.*, *Biochemistry*, **10**, 2606; 1971) but, with few exceptions, the types and functional roles of the proteins have remained obscure. In particular, the presence of proteins with an apparent molecular weight in excess of 200,000 and apparently not dissociable into smaller subunits by treatment with thiols or detergents has been rather enigmatic. One would expect that intrinsic proteins would have more non-polar amino acids than do hydrophilic globular proteins, but differences have not been impressive. Furthermore, intrinsic proteins should have relatively short hydrophilic sequences capable of reacting with lipids. Glycophorin, the major glycoprotein of the human erythrocyte, contains a peptide chain of 203 residues which completely spans the membrane and has a portion of 23 residues devoid of charged groups (Segrest *et al.*, *Biochem. biophys. Res. Commun.*, **49**, 964; 1972); but the applicability of this situation to intrinsic protein in general cannot be assessed at present.

The erythrocyte membrane is not the only system where one can find lipids and proteins in close association readily accessible for extensive study. The circulating plasma lipoproteins are important sources of avidly bound lipids and proteins that are not membrane bound. In a recent issue of *Biochimica Biophysica Acta* (**342**, 213; 1974), Langdon now reports that the apoproteins of plasma lipoproteins are major constituents of the human erythrocyte membrane.

Langdon's evidence comes from both immunological and chemical analysis of the membrane proteins. Purified, packed erythrocyte ghosts were treated with sodium dodecyl sulphate to solubilise intrinsic proteins. Then the preparation was subjected to double

Tuberculated beetle

This strange-looking beast is a male dung beetle new to science. It has been named *Amphistomus primonactus* by Matthews of the South Australian Museum, Adelaide, who discovered it in the Dorrig National Park. Its reduced hind body and exaggerated tuberculosity may be a consequence of wing reduction. It is inconspicuous and secretive, like the other wingless species of *Amphistomus*, and is abundant in closed forest leaf litter. It seems to have a very localised distribution (see *Aust. J. Zool.*, Suppl. Ser., No. 24, 1-211; 1974).

immunodiffusion on agar plates against antiserum to human density lipoprotein (apo HDL) and low density lipoprotein apoprotein (apo LDL). Strong precipitin lines indicated that the membrane proteins are related immunologically to both types of apoprotein (appropriate controls eliminated the possibility of non-specific precipitation). To determine whether the antigenic determinants resided in more than one molecular weight class, the membrane proteins were fractionated by Sephadex gel chromatography and examined by immunodiffusion. Although each protein class contained several proteins it was nevertheless noteworthy that antigenic determinants for both apo HDL and apo LDL antisera were present in all of them. Further tests showed that nearly half of the total membrane proteins are accounted for by the sum of the proteins reacting as the apo HDL and apo LDL and that probably antigenic determinants for both tested apoproteins are present in at least one protein molecule.

In order to fortify the immunological evidence with chemical evidence, end group analyses were performed. The membrane proteins were dansylated and hydrolysed and the resultant amino acids were analysed by quantitative two-dimensional polyamide chromatography. As expected, the major NH_2 terminals were aspartic

and glutamic acids, characteristic of apo HDL and apo LDL, respectively. Together they constituted 40% of the NH_2 terminals, a fact which agrees well with the immunological data, if it is assumed that most of the glutamic and aspartic acids are present as the NH_2 terminals of the apoproteins in the membrane. COOH terminals were determined by standard techniques and the results showed that these too were rich in terminal residues characteristic of the serum lipoprotein apoproteins. To discover whether the apoprotein NH_2 terminals were distributed over various molecular weight sizes, a portion of dansylated membrane proteins was fractionated by SDS electrophoresis and the amino acids from each band chromatographed on polyamide. The results showed that the characteristic NH_2 terminals of serum apoproteins were distributed over a wide range of molecular sizes, in agreement with the immunological data.

The pattern of the NH_2 terminal amino acids together with certain of the immunological data and the high molecular weights observed led Langdon to consider that the apoproteins may be linked in the membrane to form larger molecules. Previous work had shown that disulphide links are not present in membrane proteins so Langdon investigated the possibility of lysine-derived crosslinks, more usually found in connective tissue (*Biochem. biophys. Acta*, **342**, 292; 1974). He indeed found positive evidence for such links using chemical techniques similar to those used for examining proteins like collagen and elastin.

Langdon's data pose some intriguing and important questions. Are serum lipoprotein apoproteins the major intrinsic proteins of the erythrocyte by virtue of their affinity for lipids? And do they form a structural basis for the covalent attachment of enzymes and other protein types? Are the apoproteins synthesised in the haemopoietic system during erythropoiesis or are they derived from circulating lipoproteins? If Langdon's results are confirmed, they could have far-reaching implications in both membrane biochemistry and in cardiovascular research.

• Functions of the cell periphery

by Peter Newmark

By shrewd invention of a title the organisers of a discussion meeting held at the Royal Society on June 19–20 managed to attract a diverse range of speakers on the pericellular environment and its regulation in vertebrate tissues. Within this framework many topics were touched on although most

contributions were concerned with connective tissue cells and matrix.

The problems of understanding the metabolism of the matrix are based partly on the complexity of its component proteoglycans, glycosaminoglycans and tensile fibres and partly on separating the synthetic and degradative parts that connective tissue cells play in the turnover of the matrix. H. Muir (Kennedy Institute for Rheumatology, London) reported on the disproportionate importance of the minute amounts of hyaluronic acid recently shown to be present in cartilage matrix. It seems that the distinct proteoglycan aggregates found there are formed by virtue of the affinity of one end of the proteoglycan's core protein for multiple sites on the hyaluronic molecules. An additional important role for hyaluronic acid in cartilage is implied by the demonstration that it inhibits the production of proteoglycans by chondrocyte suspensions, possibly by means of a cell membrane effect.

The role of the membrane in matrix turnover was also raised by the studies of J. T. Dingle (Strangeways Research Laboratory, Cambridge). In addition to reporting on two new cathepsins that may play a part in proteoglycan breakdown, he also elegantly demonstrated that cathepsin D is localised on or around the cell membrane during its stimulated secretion from cells. A functional importance of this phenomenon was suggested by it also being demonstrated in cartilage taken from human rheumatoid arthritic joints. The importance and site of action of the cathepsins, all of which have an acidic pH optimum, however, remain to be elucidated.

P. Davies (Clinical Research Centre, Harrow) drew parallels between the development of glomerular nephritis and asbestosis. The activation of lysosomal enzymes by immune complexes in the first case and by asbestos particles in the second disease can result in the breakdown of the basement membrane. This, perhaps with contributory mechanisms, can trigger off the overproliferation of epithelial cells and thickening of the basement membrane that is associated with both diseases. Cell proliferation, in this case of the arterial smooth muscle cells, was also one of the topics discussed by R. Ross (University of Washington). When grown in culture, these cells, like so many others, only proliferate in the presence of serum. It seems, however, that the important growth factor(s) is initially derived from platelets. The importance of this factor could be that, when released from platelets at a site of arterial injury, it causes the local proliferation of subendothelial cells in atherosclerosis.

In a speculative vein J. E. Scott

(MRC Rheumatism Unit, Taplow) contemplated the evolutionary forces that may have determined the universality of polyanionic carbohydrates in cell membranes and matrix. In prebiotic times they would have produced an excellent shield against radiation-produced hydrated electrons; with the advent of aerobic conditions they would still be very stable; and, finally, they possess excellent properties for withstanding the wear and tear to which extracellular molecules are subjected.

In his continuing studies of cell-cell recognition, M. M. Burger (University of Basel) has recently turned his attention to a model system, the sponge. Suitable treatment of sponge cells results in their releasing an aggregation factor and a base plate. If the latter is covalently attached to cell-sized solid beads, the addition of the aggregation factor and calcium results in bead aggregation. This neat system promises to assist in the elucidation of the molecular basis of cell interactions.

Orientation to odours by insects

from our Insect Physiology Correspondent

It has long been known that insects fly upwind to attractive odours—mosquitos finding their hosts, drones locating the queen bee, fruit flies seeking fermenting fruit—and that the maintenance of the direction of flight is a visual response to the pattern of the ground below. In other words that anemotaxis in the flying insect is an optomotor response. But a year or two ago (*Science*, **173**, 67; 1972; **180**, 1302; 1973) Farkas and Shorey claimed that in response to the sex pheromone of the female, flying males of the pink bollworm moth *Pectinophora* are guided by a chemotactic mechanism which can operate in still air. The existence of such a mechanism of oriented flight in the absence of a moving air stream (as opposed to a kinetic mechanism dependent on gradients in the concentration of odours, or a visually oriented mechanism in an air stream) could be disturbing for accepted theories of orientation by flying insects.

Kennedy and Marsh now point out (*Science*, **184**, 999; 1974) that in the experiments of Farkas and Shorey the males were already in flight and may already have been oriented anemotactically before the air stream was stopped. They have therefore repeated the experiments on males of the dried fruit moth *Plodia interpunctella* and related moths; the movements of the insects were accurately recorded in a wind tunnel and the results were analysed statistically. The flight of male insects in a stream of air in a wind tunnel could be completely controlled by the

Two 3 s flight tracks (based on videotape records) of the same male *Cadra cautella* after its arrival by upwind flight at a point 0.50 m from a source of female scent. To the left (a): the source remained throughout the upwind position marked by the star. To the right (b): the source was removed as soon as the male reached the level of the arrowhead so that the male entered unscented air after travelling approximately 0.15 m further upwind. (Scale: 0.15m.)

movement of black and yellow stripes on the floor. If the stripes were stationary the males flew upwind against the stream of odour from the female; if the stripes moved downwind above a certain velocity the flying male also was carried downwind. If the odour was suddenly removed while the male was in flight, but the odourless air stream continued, the male arrested its upwind flight and flew at right angles to the air stream, casting to and fro over a progressively widening band (see figure). This response was unchanged if one antenna was removed, which would not have been the case if a chemotropotactic mechanism were involved.

It seems, therefore, that an odour-controlled optomotor anemotaxis is still the most plausible mechanism to account for the response of the male moth to the sex pheromone of the female; and that the side to side casting when the odour trail is lost, which had been noted in the past, is an important element in the optomotor reaction.

Anchoring the Ig molecule

from a Correspondent

It is generally accepted that immunoglobulin (Ig) acts as the antigen recognition unit at the surface of bone marrow-derived (B) lymphocytes. The chemical homology between the membrane-bound Ig and the molecules secreted by the activated antibody-forming B cell is unknown although this must be considerable since the surface-bound Ig component can be detected if serum reagents specific for both variable and constant regions are used. This raises the problem of how a soluble Ig glycoprotein molecule is

adapted to perform a function which requires firm attachment to the cell surface membrane. In many integral membrane proteins and glycoproteins a small hydrophobic segment of peptide anchors the rest of the molecule into the lipid bilayer of the membrane. It is possible certainly that the polypeptides of surface Ig contain an extra stretch of amino acids suitable for this purpose. If the two or three well studied examples of membrane proteins are considered, these amino acids would be located at the carboxyl terminal of heavy chains in the constant (Fc) portion of the molecule.

An alternative method for anchoring an essentially water soluble component to a membrane involves attachment to an integral membrane component with a recognition site for some part of the soluble protein. This method is favoured by Ramasamy *et al.* (*Nature*, **249**, 573; 1974) for surface-bound Ig.

B lymphocytes as well as macrophages, mast cells and polymorphonuclear cells possess surface receptors for the constant (Fc) portion of Ig. It is proposed that these receptors tightly bind Ig molecules to the B cell surface in such a way that the antigen binding sites of the variable region of Ig extend into the extracellular space and are available to specific antigen. The murine plasma cell tumour MOPC 21 (P3) secretes IgG1 kappa molecules in culture, a small proportion of which may be assumed to bind to and saturate the putative Fc surface receptors. Indeed, no Fc receptors are detectable on these cells. Mutants blocked in Ig secretion, however, can be obtained and these also carry no surface Ig molecules. Ramasamy *et al.* argue that in these cells the Fc surface receptors should be demonstrable and this proved to be the case. That is to say there is in general an inverse correlation between the presence of surface Ig and Fc receptors.

The surface Ig of mouse B lymphocytes is probably monomeric IgM, and it seems that the secreted pentameric IgM may have decreased affinity for Fc receptors since secreted IgM only weakly inhibits Fc rosettes on B cells. The interaction of Ig with Fc receptors also seems in some cases to require intact Ig carbohydrate units. Williams *et al.* (*J. Immunol.*, **111**, 1690; 1973) have treated rabbit IgG preparations with an endo- β -N-acetylglucosaminidase from *Diplococcus pneumoniae*. About a half of the carbohydrate, present largely in the Fc portion of the Ig molecule, is removed. The bacterial agglutinating activity of anti-pneumococcal IgG was unaffected by this treatment whereas complete loss of opsonic activity occurred. Similarly several treated IgG preparations had markedly decreased ability to inhibit

rosette formation between human monocytes (carrying surface Fc receptors) and IgG-coated erythrocytes. Not all IgG preparations were affected in this way, however, (for example, anti-streptococcal), although similar amounts of carbohydrate were removed by the glycosidase.

The reason for this finding is not clear. Since it cannot yet be excluded that the detailed carbohydrate structure of Ig molecules may differ according to species or possibly with the particular cell clones activated to produce antibody, it seems likely that the type of carbohydrate structure left behind on the treated Ig molecule may also vary. In some cases the biologically relevant sugar sequences might not be removed by glycosidase treatment. Further work using additional enzymes will be required to remove more than half of the carbohydrate, leaving the Ig polypeptide chains intact. Only then will it be feasible to decide if significant differences in the mechanisms for opsonisation and phagocytosis of different bacteria exist rather than the simpler explanation that differences in carbohydrate structure occur in Ig molecules of different specificities.

Terminal sequences of animal virus RNAs

from Alan E. Smith

To date, attempts to sequence the RNA of animal viruses have lacked the spectacular success of bacteriophage RNA sequence work. This is largely because of the difficulties encountered with animal viruses in obtaining either highly labelled RNA for analysis by the Sanger technique or large amounts of RNA for sequence determination by more classical methods. Nevertheless, methods are being developed to overcome these problems and among the most successful are the techniques for the enzymatic introduction of radioactive phosphate into specific positions within viral RNA molecules.

Silkworm cytoplasmic polyhedrosis virus (SCPV) contains ten pieces of genomic double-stranded RNA, and in this and other respects it is very similar to the more familiar reoviruses. Some time ago the nucleotides present at the ends of reovirus double-stranded RNA were determined by isolating 32 P-labelled viral RNA and subjecting this to Sanger RNA sequencing techniques. All ten fragments of reovirus were found to have a 5' terminal guanosine 5' diphosphate followed by a pyrimidine residue (*J. molec. Biol.*, **61**, 643-653; 1971) and a 3' terminal cytosine (*Nature new Biol.*, **232**, 114-115; 1971). Each genome fragment therefore

seems to have a perfect duplex form.

In a recent issue of the *Journal of Molecular Biology* (85, 31-48; 1974) Miura, Watanabe and Sugiura report a similar analysis of silkworm cytoplasmic polyhedrosis virus. To avoid the difficulties in labelling silkworms with ^{32}P to produce radioactive virus, the isolated viral RNA was treated with phosphomonoesterase to remove any 5' phosphates and then labelled in the 5' OH position using polynucleotide kinase and [$\gamma^{32}\text{P}$] ATP. The native double-stranded RNA molecules proved very difficult to label by this method, however, and to achieve efficient labelling Miura *et al.* first removed chemically two or three residues from the 3' end of the molecules, thus exposing a short single-stranded 5' terminal region. Presumably such single-stranded tails are much more accessible to enzymatic modification. The labelled molecules were then analysed by ribonuclease digestion followed by column chromatography. Two 5' termini were found and were identified as A*GU and GGC. The identity of the 5' terminal base A* is as yet uncertain but it is probably an adenosine residue with a modified 2' OH group. Such modified bases, although a common feature in transfer RNA molecules, are rare in viral RNAs. The 5' terminal sequences are consistent with perfect duplex formation in the SCPV genome since the same authors have previously identified cytosine and uridine as the 3' terminal bases.

To determine whether all of the double-stranded genome segments contain both 5' terminal sequences or if some fragments contain symmetrical ends, all of the ten genome segments were separated on polyacrylamide gels and then individually subjected to end-group analysis. This showed that every fragment contains both sequences and suggests that each has the structure

As with reovirus, silkworm cytoplasmic polyhedrosis virus particles contain an RNA-dependent RNA polymerase which actively transcribes the double-stranded RNA into messenger RNA *in vitro*. All ten mRNA molecules made *in vitro* by the reovirus enzyme begin with ppG (Banerjee, Ward and Shatkin, *Nature new Biol.*, 230, 169-172; 1971). Further sequence data on highly labelled mRNA made from the smaller double stranded RNA segments has been presented by Nichols, Hay and Joklik (*Nature new Biol.*, 235, 105-107; 1972). Some 5' terminal guanosine triphosphate as well as diphosphate was detected in this study, but no protein synthesis initiation codon was present within the first 25

A larger Gondwanaland?

from Peter J. Smith
Geomagnetism Correspondent

ALTHOUGH the principal features of the ancient supercontinent of Gondwanaland are now widely accepted, there are still some details (if whole countries may be so regarded) and disagreements to be settled. One outstanding problem, for example, concerns the present position of the continental crust which once lay between Australia and India. Somewhat less of a problem in many people's eyes is the nature of the present join between India and the rest of Asia. Dewey and Bird (*J. geophys. Res.*, 75, 2625; 1970) suggested that the Himalayas resulted from continental collision; and such has been the influence of the article in which this proposal appeared that some of the difficulties with this interpretation have perhaps not been given the attention they deserve.

At least, that seems to be the view of Crawford (*Science*, 184, 1179; 1974) who cites Meyerhoff's claim (*J. Geol.*, 78, 1; 1970) that there is evidence against India's colliding with the rest of Asia. Certainly, there are problems here, which is why Powell and Conaghan

(*Earth planet. Sci. Lett.*, 20, 1; 1973) recently proposed that although the Himalayan mountain chain is basically of the collision type, it was not formed as a direct result of the collision. But Crawford, who at the time of writing was apparently unfamiliar with the Powell-Conaghan model, goes further in proposing that the Himalayas formed intracontinently and arguing against collision on the grounds that the Indus Suture Line, "if it is the relic of oceanic subduction preceding collision, lies on the wrong side of the Himalayas".

In Crawford's reconstruction, Gondwanaland was originally larger than is usually supposed and included Tibet, the Tarim Basin block and parts of northern China. It was Tibet, in fact, which lay between India and western Australia in the form of submerged continental crust. The Indus Suture Line is then seen as "a relic of a Permojurassic oceanic opening to the mantle" which closed at the end of the Jurassic. The Himalayas later developed along fractures which had formed parallel to the opening of the Indus Suture Line.

Precursors of strike-slip faulting

from Peter J. Smith
Geomagnetism Correspondent

THE travel-time residuals of seismic waves—the differences between observed arrival times and the corresponding arrival times computed using a standard Earth model—are due (in addition to random experimental errors) partly to imperfect source determination and partly to differences in velocity between the real Earth and the assumed model. But if at a particular seismograph station the residuals from many sources at many different locations are averaged, the random errors associated with particular wave paths and particular sources should cancel out, thereby making it possible to isolate the common part of the residuals arising from velocity deviations in the crust beneath the station. If the seismic events concerned are also well distributed in time, it should then be possible to determine any secular variations in the near-station contribution to the residuals, and even to determine changes in the near-station crustal velocity (given the source volume).

5' terminal residues sequenced.

Shimotohno and Miura (*J. molec. Biol.*, 85, 21-30; 1974) now report that the 5' sequence of the RNA made by the silkworm virus enzyme is ppAGPy, and this unique sequence is present in the mRNA transcribed from each of the genome fragments. This indicates that transcription to make mRNA begins at the first base of each molecule, reading from the strand with the 3' OH sequence PuCU. Perhaps the unusual base at the 5' end of the complementary chain plays some part as a recognition site for the binding of the polymerase molecule.

It would be interesting to determine whether the 5'-terminal A in mature mRNA is modified, since the presence or absence of such a modification might be used to distinguish between molecules destined to be messengers from those making up progeny genomic RNA. So far studies on reovirus multiplication have shed no light on the distinction between transcription to give mRNA and replication to give double-stranded RNA, nor on how they are controlled relative to one another. Apparently, the presence of poly (A) in the mRNA species cannot be used as a distinguishing feature since reovirus mRNA does not contain this appendage (*J. biol. Chem.*, 248, 7993-7998; 1973).

Applying this technique to 3,000 P wave residuals for events in the Matsushiro area of Japan during the period 1960-1968, Wyss and Holcomb (*Nature*, **245**, 139; 1973) were able to show that the Matsushiro series of earthquakes of 1965-1966 had been preceded by an anomalous decrease in P wave velocity in the source region. Specifically, the P wave residuals began to increase significantly from the long term average of -1.25 s around October 1962 (about 3 years before the earthquake series began), representing a decrease in P wave velocity near the Matsushiro station of about 20% (assuming a source volume with a radius of about 16 km). The residuals then returned to within one standard deviation of the long term average about 330 d before the Matsushiro swarm began and about 770 d before the swarm's principal energy release.

At the time that Wyss and Holcomb were carrying out their analysis they were apparently aware that premonitory changes in seismic velocity in earthquake source regions had already been observed in the Soviet Union, New York State and the Transverse Ranges of southern California; and so in that sense they were neither reporting a new phenomenon nor pointing out for the first time its possible application to earthquake prediction. On the other hand, the Matsushiro result was more than just another example of a known effect, for it was the first time that premonitory velocity changes had been observed before strike-slip faulting.

Not the least interesting aspect of this discovery was that, at about the same time, several groups of workers were attempting, and apparently failing, to find comparable premonitory changes along the active central section of the San Andreas fault—and Nur *et al.* (*Stanford Univ. Publs. geol. Sci.*, **13**, 391; 1973) had even suggested that the explanation for velocity changes in terms of dilatancy may not be applicable generally to strike-slip faults.

But all that has now changed, for Robinson *et al.* (*Science*, **184**, 1281; 1974) report that, using P wave residuals as indicators, they have been able to observe changes preceding the Bear Valley earthquake of February 24, 1972 (surface magnitude, 5.0). The travel-time residuals analysed were from small local earthquakes which occurred along the Calaveras fault north-west of the Bear Valley region between June 1, 1971 and May 30, 1972 and which had been located precisely using the US Geological Survey's network of seismograph stations, excluding the three stations (BVL, which lies almost above the focus of the Bear Valley earthquake, and the nearby EKH and JHC) at which the residuals them-

selves were observed. In all, 49 shocks were observed sufficiently well at BVL and a slightly smaller number at each of the other two stations.

The expected range of 'normal' residuals about their mean value was ± 0.15 s; and for most of the one year observation period, residuals were indeed within these limits. But between late December 1971 and late January 1972 the residuals at BVL were anomalously high at about 0.3 s above normal values and, in the statistical sense, significantly higher on average than the mean for the preceding 7 months. As the eight events within the anomalous period covered a distance range of 50 km (20-70 km), a magnitude range of 2.7 (0.7-3.4) and a depth range of 7 km (2-9 km), and were apparently no different in such respects from the other events, there seems little reason to doubt that their anomalous nature represents a genuinely precursory indication of the February 24, 1972 earthquake.

Unfortunately, data from the other two stations were ambiguous, with only two of the seven residuals within the December-January period at EKH and none of the five corresponding residuals observed at JHC lying outside the 0.15 s limit, and so to that extent confirmation was lacking. But accepting the BVL results, Robinson and his colleagues conclude that the anomalous changes in residuals are equivalent to a 10-15% decrease in P wave velocity within a volume having the same radius (7 km) as the observed aftershock zone. This decrease began 60-53 d before the Bear Valley shock itself, which is consistent with the time scale deduced for a magnitude 5.0 event using other methods. And as seems to be usual in such circumstances, the velocity returned to its normal value before (in this case several weeks before) the onset of the main event, although the data are not sufficient to indicate whether this return was sudden or gradual.

Naturally, this result raises the interesting question of why other workers (using different methods) have failed to observe premonitory changes, even when investigating the same earthquake: McEvilly and Johnson (*Science*, **182**, 588; 1973) for example, examined the stability of P wave travel times along a path passing about 10 km north of Bear Valley, and concluded that the 1972 Bear Valley shock was preceded by no significant changes. In this case, however, failure seems to have been simply a matter of bad luck. McEvilly and Johnson made use of quarry blasts as sources; but unfortunately, as Robinson *et al.* point out, no blast actually took place during the anomalous period now recognised from the BVL residuals.

Octupole states in cadmium

from Peter E. Hodgson

Nuclear Theory Correspondent

THE energies, spins and wavefunctions of low lying nuclear states can often be calculated from a simple model, and it then becomes particularly interesting to see if they can be found experimentally. If some of them are predicted by one model but not by another, they become important for deciding which of the models is to be preferred.

An example of such a state is the 3^- octupole state expected on the collective vibrational model at about 2 or 3 MeV in heavy nuclei. Such states had been found in the even isotopes of cadmium, and this was accepted as evidence for the collective nature of these nuclei.

Collective states are strongly excited by inelastic scattering. The energies of the inelastically scattered particles give the energies of the nuclear states, and their angular distributions and intensities give the quantum numbers and strengths of the states. In the case of vibrational nuclei the strength of a state is related to the dynamic deformation. The work on ^{110}Cd showed a 3^- state at 1.9 MeV with a strength similar to that expected from the collective model.

This has now been challenged by some accurate new measurements by Gill and colleagues at the University of Alberta (*Phys. Rev. Lett.*, **32**, 889; 1974) of the energies of the γ rays emitted after the inelastic scattering of neutrons by ^{110}Cd . As shown in Fig. 1, they found γ rays of 1,404, 1,409 and 1,416 keV, corresponding to the decay of states at 1,917, 1,923 and 1,930 keV to the state at 513 keV. None of these states decays to the ground state to a detectable degree. Thus, what was previously interpreted as a single 3^- state is now resolved into three separate states with quite different properties. As shown in Fig. 2, the sum of the inelastic scattering cross sections to these three states is similar to that expected from a single

Fig. 1 Spectrum of γ rays after the inelastic scattering of neutrons by ^{110}Cd , showing the line at about 1,410 keV resolved into three peaks.

3^- state, but individually they correspond to 0^+ states. Thus the evidence previously interpreted as indicating a single 3^- state is now re-interpreted in quite a different way. There is no other state in the required energy region that could plausibly be interpreted as the required 3^- collective state, so the evidence for the collective nature of this nucleus is weakened.

This result is important for the understanding of the structure of cadmium, but it has several wider implications. First, it is a reminder of the importance of precision in physical measurement. Time and again increased precision does not merely sharpen the picture, but reveals wholly unexpected details that oblige one to adopt a completely new interpretation. Second, it is a reminder of the provisional nature of much of the day-to-day details of scientific work, particularly on the frontiers of knowledge. In so many cases scientists build ideas on quite flimsy and scattered evidence; it is right for them to do this provided they realise how subject it is to revision in the light of new information.

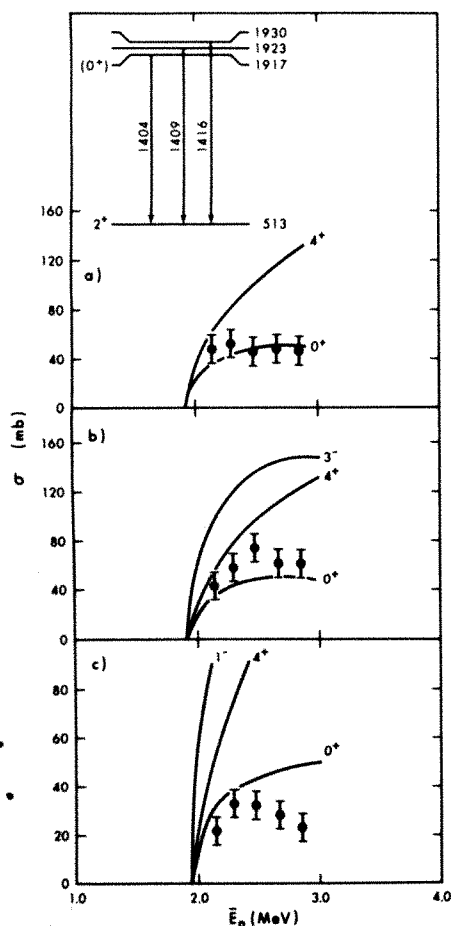

Fig. 2 Excitation functions for the total cross sections for the excitation of the states of 1,917, 1,923 and 1,930 keV by inelastic neutron scattering. The sum of the individual intensities is compatible with 3^- , but individually they cannot be 3^- and are likely to be 0^+ .

It is never sufficient to be satisfied with an interpretation that explains the incomplete set of experimental data available. Every consequence of an interpretation needs to be tested as rigorously as possible, and even then one must be prepared for the new unexpected result that calls it all in question again.

Acceptable radiation exposure

from J. R. A. Lakey

THE chairmen of both the International Commission on Radiological Protection (ICRP) and its counterpart on Radiation Units and Measurements (ICRU) were opening speakers at the Society for Radiological Protection International Symposium held at Aviemore, Scotland from June 2 to 6. These two commissions provide the ground rules for all aspects of radiological protection and both place considerable stress on the measurement of radiation and its interpretation.

C. G. Stewart (ICRP) opened the symposium with a statement on the ICRP recommended Investigation Levels and Derived Working Limits and described these as signposts to direct action which could also be used as criteria for discarding unnecessary information. Radiation exposures exceeding these levels demand more careful consideration and higher accuracy of measurement. J. Dunster (National Radiological Protection Board, Harwell) endorsed this thesis and said that errors of a factor 2 are acceptable in some radiation measurements but this does not excuse lack of clarity in thought on the part of the health physicist.

P. J. Campion (National Physical Laboratory, Teddington) described metrology as the cornerstone on which all advances in radiological protection could be built. In addition to the necessity for instrument calibration he stressed the need for a strict hierarchical structure so that the calibration of a particular instrument could be traced back to the national standard. R. Maushart (B. F. Vertriebes, Karlsruhe) appealed for standardisation of the methods of using instruments so that calibration is not an end in itself.

H. L. Wyckoff, the chairman of the ICRU (Washington DC) presented an elegant resumé of the quantity of dose equivalent which has been jointly developed by his commission and the ICRP. This quantity is expressed in the rem unit, derived from the absorbed dose with corrections depending on the nature of the radiation.

R. H. Mole (MRC Radiobiology Unit, Harwell) agreed that a relation-

ship must exist between the absorbed dose of radiation and the degree of probability of an effect on the exposed person. Philosophical problems emerge when risks to population are computed by the summation of risks to individual members. It is particularly difficult to place these computed population risks into perspective and a great deal has yet to be learned about public acceptance of these estimates. On the other hand the concept of risk or detriment to an individual organ of the body is useful for the summation of radiation exposure to the body due to intake of a single radionuclide. J. Vennart (MRC Radiobiology Unit, Harwell) said that this estimate of risk could be derived from the forthcoming ICRP recommended Maximum Permissible Annual Intake which is to replace the less satisfactory Maximum Permissible Body Burden. He said that the commission would also publish Derived Air Concentrations but there was to be no attempt to give limits for drinking water for occupationally exposed persons, who, after all, consume the same water as the public.

The legal attitude to radiation protection varies between countries to the extent that the radiation worker could be restricted in mobility and so the European Economic Community aims to improve this situation through its directives to member countries. These proposals, summarised by P. Recht (EEC), are expected to involve some changes in United Kingdom legislation in spite of the common ICRP basis. A. W. Kenny (Department of the Environment, London) also showed that the EEC would become a new factor in the control of radioactive waste. The UK approach presented by A. Preston (Fisheries Laboratory, Lowestoft) is to limit radioactive waste disposal by restricting radiation exposure to members of a critical population group. The main difficulty in the application of this procedure is the need to find a completely objective method of selecting the critical group. W. D. Rowe (US Environmental Protection Agency, Washington DC) described an alternative approach which makes use of comprehensive mathematical models which include source terms, environmental transport pathways and human metabolism to predict the dose to members of the public. These models require some form of measurement for their periodic validation but might avoid some of the problems of the critical group method.

Preprints of most of the papers which were presented can be obtained on payment of a small fee from Mr K. B. Shaw, National Radiological Protection Board, Harwell, Didcot, Berkshire OX11 0RQ.

Chronological and ecological implications of the fossil Bovidae at the Sterkfontein Australopithecine site

E. S. Vrba

Transvaal Museum, PO Box 413, Pretoria, South Africa

Bovid remains indicate the presence at Sterkfontein of three faunal phases, accumulated at different times and probably under different climatic conditions. These phases are variously associated with such well known Sterkfontein finds as the type locality australopithecine assemblage, the West Pit (extension locality) hominid remains which may include Homo and numerous stone artefacts.

SEVERAL hundred bovid cranial fragments, mostly dentitions, hailing from the various localities at the Sterkfontein excavation site (see Fig. 1), were available for this study. Associated with the famous australopithecine material at the Sterkfontein main quarry (type locality—henceforth referred to as STS)—were 111 specimens. Forty-two specimens came from the West Pit (extension locality, SE), which was excavated by J. T. Robinson in 1957 and 1958 (ref. 2). Some 200 specimens came from rubble dumps D1, D2, D3, D5, D6, D8, D12-16 and H2, excavated by P. V. Tobias and A. R. Hughes, who placed these materials at my disposal for study. These dumps, STS and SE will be referred to throughout this work as site units. The bovid species identified at Sterkfontein are shown in Table 1.

Of primary interest in this study is what information the Bovidae can provide about a possible time difference between the two main hominid-bearing site units, STS and SE. It has been suggested that SE may belong to a later time period than STS. Robinson² wrote of the presence at Sterkfontein of an earliest Lower breccia including STS, which he believed to be unconformably overlain by a later Middle breccia including SE. He also recognised a third, youngest Upper breccia. Tobias⁴ felt that unlike STS, the SE assemblage includes at least a trace

of a hominid more advanced than *Australopithecus*. An important contribution to any discussion of the affinities of STS and SE is the fact that many stone tools have been recovered from SE. They were first discovered there by Brain⁵, and have since been found in numbers totalling hundreds at SE and in several dumps. None has been found in association with *Australopithecus* at STS. The first published suggestion that some major South African fossil assemblages can be arranged in a succession of Faunal Stages (this was later amended to Faunal Spans⁶) came from Wells⁷, who included STS in the earlier Sterkfontein stage and SE in a later Swartkrans stage. This is the first time that Sterkfontein faunal remains have been included in the

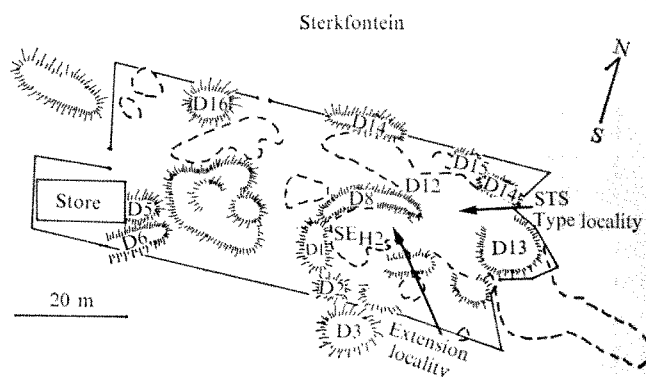

Fig. 1 Plan of the Sterkfontein Excavation Site (after Tobias and Hughes¹). SE, West Pit; D1-16, rubble dumps; H2, material excavated under SE; - - - caves, holes and excavations.

discussion of the contemporaneity or otherwise of STS and SE.

To date there has been no published attempt to relate the fossil content of the rubble dumps to the *in situ* breccia of Sterkfontein. If the Sterkfontein fauna was really assembled during successive time periods, whether in a series of breccias as visualised by Robinson or as part of a continuous breccia,

it has to be concluded that the contents of the rubble dumps may be mixed with respect to such time periods. Nonetheless any one dump should contain a high proportion of fossils from a single part of the deposit, and so from a single time period. An attempt is made here to group these dumps, on the basis of their bovid fossil content, with each other and with STS and SE.

Line thicknesses represent minimum number percentages per species per site as follows:

----- Only one or two specimens present which are suspected of belonging to a different faunal phase

Fig. 2 Distribution of bovid species between STS and SE. The specimens here represented are only those deriving from *in situ* STS and SE breccia. *Damaliscus* sp. of Table 1 and Fig. 4 is divided into *Damaliscus* sp. 1 or *Parmularius* sp., and *Damaliscus* sp. 2; nearest extant relative given in each case; E, extinct; IR, indistinguishable from recent.

Statistical methods and results

In site units STS and SE species, as represented in Table 1, were separated into five tribes or tribal groupings: Hippotragini; Ovisovini; Alcelaphini; Antilopini and Neotragini; Bovini, Tragelaphini and Reduncini. A chi-square test showed that, in terms of the minimum number contents within these tribal groups, STS differs significantly from SE ($\chi^2_4 = 11.84$; $\chi^2_4(0.05) = 9.488$).

The tribes Alcelaphini and Antilopini are widely recognised as generally forming the bulk of any open plains-grassland fauna. For STS and SE the percentages which the added minimum numbers of these two tribes constitute of the total minimum numbers were found to be 48% and 82% respectively (Fig. 2). A chi-square test performed on these data showed that the SE assemblage has a highly significantly larger proportion of alcelaphines and antilopines ($\chi^2_1 = 7.17$; $\chi^2_1(0.01) = 6.635$) than has the STS assemblage.

Two types of distance functions were used to express affinity, in terms of minimum numbers per species, between all pairs of site units in Table 1. The first, here named FCD for 'faunal composition difference' coefficient, was arrived at as follows: if the taxa (species) are coded $i = 1, \dots, I$ and the site units $j = 1, \dots, J$ and if x_{ij} denotes the minimum number of individuals of species i at site unit j , then the FCD between site units m and n , denoted by D_{mn} , is calculated as

$$D_{mn} = \sum_{i=1}^I |P_{im} - P_{in}|$$

where $P_{ij} = \frac{x_{ij}}{x_{.j}}$, $j = 1, \dots, J$, where $x_{.j}$ denotes the sum of x_{ij}

over i . FCDs range from 0 to 2. The second distance function used was χ^2 . Each of the two functions was calculated (a) for all pairs of site units over all separate species categories 1–24; (b) for all pairs of site units over separate species categories 1–11 and 16–24, but lumping 12–15 into a single category; (c) for all pairs of site units with total minimum numbers ≥ 3 over all separate species categories 1–24; (d) for all pairs of site units with total minimum numbers ≥ 3 over separate species categories 1–11 and 16–24, but lumping 12–15 into a single category. The resulting matrices of FCDs and χ^2 values were clustered by the Weighted Pair Group Method Clustering Procedure⁸ into several dendrograms. An example is given in Fig. 3. Without exception the dendrograms showed the most fundamental split to be between STS, together with D13, D14 and D15, and the rest. A further split among the remaining site units was consistently indicated between SE together with H2, D1 and D5 on the one hand, and D16 together with D8 and D6 on the other. The placement of D2, D3 and D12, each with a total minimum number of 1, varied, but they were always separate from the STS cluster. Figure 4 shows the three faunal phases represented by site units, as suggested by these methods. It must be borne in mind that the low minimum number content of some of the site units limits the confidence that can be felt in the accuracy of their placement.

Bovoid faunal phases

A comparison between Figs 1, 3 and 4 shows an interesting correspondence between the geographic location of site units and their grouping on bovid content, with the possible exception of D5 and D8. Nonetheless there remains a greater measure of uncertainty with respect to the homogeneity of the dump assemblages than is the case with STS and SE. It is therefore useful to look first at the bovid species distribution between faunal phases A and B as represented only by STS and SE (Fig. 3). The dominant species at STS are: *Makapania broomi*, which is also among the most common species at the Makapansgat Limeworks⁹; a large new hippotragine species, which could be ancestral to *Hippotragus gigas* known throughout the Olduvai Beds and at Elandsfontein in South Africa; and a small alcelaphine which could be close to, or specifically identical to, a species from the East Rudolf *Metridiochoerus*

Fig. 3 Dendrogram of the relations among 14 site units based on WPGM clustering procedure⁸ using FCD values. Site units as in Fig. 1, each accompanied by its minimum number content.

andrewsi zone¹⁰. Each of the three species is represented doubtfully in the SE assemblage by a single broken specimen. At SE can be seen the first occurrence in the Sterkfontein context of the distinctive dentitions indistinguishable from the extant *Damaliscus dorcas*. *Antidorcas bondi* and *Damaliscus* sp. 2, which is likely to be *Damaliscus niro* (my unpublished work), probably also make their first appearance at SE, if the single specimen of each from STS is indeed misplaced in that assemblage as I strongly suspect for several reasons. On the whole, in view of the markedly greater affinity to Makapansgat of STS than of SE, and the implications of the χ^2 test results, the bovid assemblages of STS and SE seem to be essentially different and successive in time.

Figure 4 shows that inclusion of the dumps amplifies differences between faunal phases A and B, and adds a third phase. Faunal phase C, as represented mainly by D16 is undoubtedly distinct in its general character from phase B, and probably considerably later in time. There is here the advent at Sterkfontein of several species that are indistinguishable from recent forms. Only two phase C species are definitely extinct: *A. bondi* and the 'larger small' *Damaliscus* sp., which again in phase C very likely belongs to *D. niro* (my unpublished work). *A. bondi* and *D. niro* are generally among the few extinct bovid species at southern African Middle Stone Age sites.

It seems that at least a large part of the differences between these three bovid faunal phases, accumulated in close geographical proximity and signalling the advent of new 'indistinguishable-from-recent' species with each successive phase, is due to time. Phase A, associated with the STS australopithecine assemblage, belongs with Makapansgat in the Sterkfontein Faunal Span. Phase B, associated with the SE hominids which might include at least some *Homo*, resembles both Kromdraai A (the faunal site) and Swartkrans with respect to its high alcelaphine-antilopine content, although it is perhaps closer to the latter in terms of species present. It could belong to the Swartkrans or to the Cornelia Span. Relevant here is the simi-

larity of tool forms from both SE and Swartkrans to the developed Oldowan assemblages¹¹. Phase C could belong to the Florisbad⁷ or Florisbad-Vlakkraal Faunal Span⁶ of Middle Stone Age time. In my thesis for the University of Cape Town, I am making a more detailed attempt at bovid faunal correlation

between the Sterkfontein phases and the other Krugersdorp sites. Tobias¹² has reviewed the dating of the South African australopithecine sites, linking the results of new geomorphological studies to what has so far been concluded on the basis of faunal comparisons.

Fig. 4 Suggested distribution of bovid species throughout all site units at Sterkfontein. E, extinct; IR, indistinguishable from recent.

Are there differences between phases A, B and C as here constituted, other than those resulting from time? In phases A and C, rather than B, there seem to predominate forms that are identical with or close to extant species that are to a greater or lesser extent bush-loving and water-dependent, like the roan antelope, reedbuck, buffalo, nyala, sable antelope and bushbuck. This is correlated with the significantly higher percentage of alcelaphines and antilopines in phase B. Although Fig. 4 makes it clear that some degree of open grassland existed near Sterkfontein during all three time periods, the data strongly suggest that during phase B there was proportionately less bush cover than during A and C. One possible cause of such vegetational change could be a decrease in rainfall between A and B with a subsequent increase in phase C. Brain⁵ concluded, on the basis of determinations of the sand grain angularity and chert-quartz ratios of the australopithecine breccias, that a general increase in rainfall, with minor fluctuations, occurred in the Sterkfontein valley from STS times onwards. An explanation for the bovid data in Fig. 4 invoking bush cover changes as a result of rainfall changes would thus seem to stand in contradiction to Brain's findings between phases A and B, while agreeing with them between B and C. Another strong possibility is that the apparent vegetation changes are largely or entirely due to a drop in temperature between phases A and B with a subsequent increase towards C.

From this perspective, therefore, it can be said that the Sterkfontein bovid fossils show evidence of having been accumulated not only at three different times but also under varying ecological, more specifically bushcover, conditions, the latter probably resulting from temperature and/or rainfall changes.

A further difference between phases A and B must be mentioned here. Individuals in phase A have a larger average body-size than do those in phase B. Although it is not impossible that

this effect is at least to some extent correlated with the ecological differences that were deduced on the basis of species content, it leads to speculation about a possible accumulation difference: for instance, the phase A bovid remains could largely be the result of the activities of a predator, such as a sabre-tooth cat, specialised for eating large prey. Perhaps the predominant influence contributing to the phase B bovid assemblage was the advanced hominid, who in spite of his tools may have been confined to small to medium-sized prey. Detailed studies by C. K. Brain of the mode of accumulation of the australopithecine bone assemblages, and my further studies of their bovid faunas, may throw light on such questions.

I thank Dr N. F. Laubscher of the Council for Scientific and Industrial Research (Pretoria) for discussions on the mathematical aspects of this work. I also thank Professor P. V. Tobias, Mr A. R. Hughes and Dr C. K. Brain.

Radiometric ages of late Cainozoic basalts from northern Israel: chronostratigraphic implications

G. Siedner*

Department of Geology, Hebrew University of Jerusalem, Israel

A. Horowitz

Institute of Archaeology, Tel Aviv University, Israel

K-Ar dating of volcanics in the Jordan rift allows an estimation of the ages of widespread stratigraphic events in the eastern Mediterranean region. The data provide a link between Pleistocene deposits of Europe and Africa suggesting, in particular, age limits to the early Acheulian and Mousterian cultures.

BASALT volcanism of late Cainozoic age is widespread in the western part of the Arabian peninsula, along a zone trending NNW from the Red Sea into Turkey. One of the most prominent occurrences of this volcanic phase is the Jebel Druze basalt province, in which lavas, covering about 48,000 km², extend south-eastwards from Lebanon to Israel, through Syria

and Transjordan, into Saudi Arabia. K-Ar ages have been determined on basalts occurring in the north-western extremity of the province and five eruptive phases, interbedded with late Cainozoic sediments of the northern Jordan Valley and the Valley of Jezre'el, are distinguished. Our data include representative samples of the chief units throughout the late Cainozoic volcanic sequence exposed in this region, with the possible exception of some of the most recent flows from the Golan Plateau (Figs 1 and 2). The present dating project thus enables radiometric ages to be allocated to many late Cainozoic sedimentary formations and stratigraphical events on the eastern seaboard of the Mediterranean.

K-Ar age determinations

The rocks investigated here have the chemical and mineralogical characteristics of alkali olivine basalts, closely similar to those described from the Jebel Druze and other Cainozoic localities

*Present address: Department of Geodesy and Geophysics, Madingley Rise, Cambridge, UK

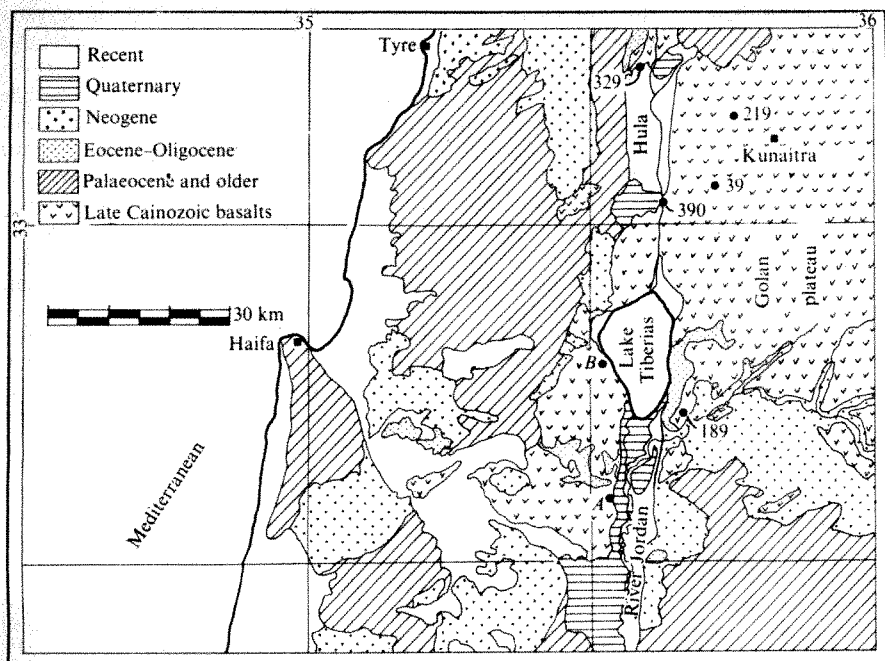

Fig. 1 Geological sketch map of northern Israel. Numbers indicate the locations of dated specimens. A, Belvoir section; B, Tiberias section.

in Transjordan^{1,2}. The analysed specimens from the northern Jordan Rift, represented in Table 1, are nonamygdaloidal, fine grained and commonly porphyritic. The phenocrysts are mostly olivine which occurs either alone or accompanied by augite and labradoritic plagioclase in various proportions. The matrix includes plagioclase in the range andesine-labradorite, augite, olivine and, in some varieties, nepheline with analcite (ref. 3, and I. Brenner, unpublished work).

Argon isotope ratios were measured statically on a Varian GD-150 mass spectrometer, equipped with a vibrating reed electrometer, using an Ar-38 enriched spike. A correction of 295.5 for the atmospheric ⁴⁰Ar : ³⁶Ar ratio was used in calculating the ages. Peak magnitudes were calculated by extrapolation

from successive scans back to the opening of the Ar-extraction line to the mass spectrometer. The decay constants adopted were

$$\lambda \beta = 4.72 \times 10^{-10} \text{ yr}^{-1}$$

and

$$\lambda e = 0.584 \times 10^{-10} \text{ yr}^{-1}$$

and the ⁴⁰K : K ratio = 1.19×10^{-2} atom %. Potassium was determined by atomic absorption on a Perkin-Elmer 303 instrument, using a bracketing procedure for calculating the results. The errors in the individual ages (Table 1) reflect analytical uncertainty only and were calculated for each analysis at the one-sigma level, following the method outlined by McDougall *et al.*⁴.

In spite of the large errors shown for the Quaternary basalts, which mainly reflect the high level of atmospheric argon contamination, the calculated ages are clustered closely into groups differing by an order of magnitude, and are in excellent agreement with available stratigraphic evidence. Thus, on the present data, the pattern of the post-Middle Pliocene volcanism in the northern Jordan Valley region seems to have comprised several intense but discrete episodes.

Stratigraphy

The earliest manifestations of Cainozoic volcanism in the Jebel Druze igneous province are provided by several basalt horizons of Eocene and Miocene age penetrated by boreholes in Transjordan¹. Near Tripoli and Damascus, Neogene volcanism began in the Middle Miocene⁵ and on the northern side of Wadi Sirhan, in north-western Saudi Arabia, several extensive basalt flows have yielded an average K-Ar age of 12.3 Myr (ref. 6). In northern Israel some 500 m of Lower Basalt flows of Middle Miocene age (Table 1) interdigitate with fluvial sediments of the Herod Formation⁷. The latter correlates with the Hazeva Formation of the Negev, which interfingers in the Be'er Sheva area with Middle Miocene marine sediments of the Ziqiaq Formation^{8,9,25}. The Herod and Hazeva Formations are regarded as representing the maximum extent of the Middle Miocene marine transgression²⁵. Sediments from the Barada Valley near Damascus, which resemble the Herod Formation in age and lithology, and include interbedded basalt flows, have been described by Dubertret⁵. The dated flows of Lower Basalt occur on the western rift scarp of the northern Jordan Valley, at the Belvoir and Tiberias sections (Fig. 1) and are 12.2 to 14.6 Myr old. The flows may be regarded as essentially coeval, with a mean age of 13.1 Myr.

The Herod Formation is unconformably overlain by the Bira and Gesher Formations, within which several flows of the Intermediate Basalt are intercalated. The latter has been described by Schulman⁷ for the central Jordan Valley, and by Horowitz¹⁰ and Fleischer (Subsurface geology of the Hula, Geol. Surv. Ist. Rep., 1968. Unpublished) for the Hula Valley and Korazim Block, respectively. The Bira Formation, mainly lagoonal chalks and marls, interfingers westward in the Yizre'el Valley with marine sediments bearing a typical Pliocene fauna^{8,11,12}. Bira sediments of the central Jordan Valley, where the dated flow is located, are interpreted as representing the Tabianian stage of the Mediterranean Pliocene²⁵, as recently defined¹³. At Belvoir a single flow was sampled at three locations about 100 m apart in order to test the reproducibility of our measurements. Individually calculated ages of the Intermediate Basalt agree to within about 3% of their mean of 4.8 Myr.

Volcanism recommenced throughout the Jebel Druze province with the formation of plateau basalts which inundated wide areas in north-western Transjordan, south-western Syria, Lebanon, and north-eastern Israel. In the last of these areas the Cover Basalt commonly attains thicknesses of 100 to 150 m and most sections show at least 10 flows, each 10 to 20 m thick⁷. The Cover Basalt is separated by an erosional unconformity from underlying Pliocene formations and is itself overlain by Guenzian sediments of the Jordan Valley^{10,25}. No sediments interfinger with the Cover Basalt, but it has been stratigraphically correlated with the preglacial Pleistocene formations of the Coastal Plain, Judea and the Negev in Israel²⁵. Ages determined on flows from near the top of the Belvoir and Tiberias sections agree closely and have an average age of 1.8 Myr.

The results given here enable us to distinguish two age groups in the post-Cover Basalt volcanics: one with an average age of 0.66 Myr, the other much younger at near 72×10^3 yr. Carbon-14 dates from bones buried within the youngest lavas on the Syrian Jebel Druze indicate an age of 4.5×10^3 yr (ref. 14). In the Hula Valley, Quaternary basalts occur in tilted blocks, interbedded with Pleistocene deposits and, on the northern border, as flat-lying sheets which can be traced to the Golan

Plateau. The Yorda Basalt^{11,15} flowed over the Korazim-Gadot block, south of the Hula Valley, filling erosional features in the Guenzian Gadot Formation and in the Mindelian Mishmar Hayarden Formation. The faulted and tilted Yorda basalt is unconformably overlain by the Rissian Benot Ya'akov Formation. Its stratigraphical age should, therefore, correspond to the late Mindel or the early stage of the Mindel-Riss interpluvial. The Yorda Basalt has been correlated by Horowitz¹⁰ with the Yarmuk Basalt¹¹ of the central Jordan Valley. Radiometric ages of these basalts are 0.64 and 0.68 Myr respectively.

The youngest extrusive episode studied by us is represented by two flows from the Golan Plateau and one from the northern Hula Valley, all of which are coeval within the analytical error, with a mean age of 72×10^3 Myr and normal magnetic polarity (D. Mor, personal communication). The Hasbani Basalt covers the upper Hula Valley¹⁵, extending northwards into Lebanon and eastwards to its probable source in the Golan. This basalt, sampled as a surface flow near Qiriat Shemona (1B-329), has been traced to the Banias waterfall¹⁰ where it separates two travertine layers. The underlying Kefar

Yuval Travertine contains late Acheulian implements and corresponds stratigraphically to the Rissian Benot Ya'akov Formation of the Hula Valley¹⁰. The Dan Travertine overlies the Hasbani Basalt and can be correlated with the Würmian Ashmura Formation of the Hula Valley which contains implements of Mousterian to Epipalaeolithic age, and with the Roqqad (or Naharayim) Basalt¹⁶ of the central Jordan Valley with which it is stratigraphically analogous¹⁰. The Hasbani Basalt thus constitutes a precise marker for the calibration of the Riss-Würm interpluvial. The age of 73×10^3 yr indicated for this phase agrees with estimates of sedimentation rates and radiocarbon age determinations of the Würmian sequence in Israel^{8,10,17}. The sampled flows from the Golan Plateau do not interdigitate with any sediments and are not subject to direct stratigraphic control, but their radiometric ages clearly show that they correlate with the Hasbani Basalt.

Discussion

The maximum development of the Miocene marine transgression in the Mediterranean region, allocated a Middle Miocene age by Gignoux¹⁸, has been shown by our dating of the Lower Basalt to have occurred between 12.2 and 14.6 Myr ago, which is in good agreement with evidence from other regions¹⁹. The Tabianian marine transgression, represented in Israel by sediments of the Pliocene Bira Formation, which are about 4.8 Myr old, is thought to have been very rapid, and to have reached its maximum extent within about 0.5 to 0.75 Myr (ref. 20).

The age of the Cover Basalt is relevant to the dating of the preglacial and the beginning of the Pleistocene glacial stages. The dated specimens were collected from the upper flows of this volcanic sequence and represent the end of the preglacial Pleistocene, about 1.7–2.0 Myr ago. The reversed magnetic polarity of the upper section of the Cover Basalt, and the consistently normal polarity of its lowermost flows^{21,22}, strongly suggests that its eruption straddled the transition from the Gauss Normal to the Matuyama Reversed epochs, estimated at 2.4 Myr (ref. 23). The beginning of the preglacial Pleistocene therefore predates the polarity transition and we propose, provisionally, to allocate it an age in the range 2.6 to 3.0 Myr—a date which also corresponds to the close of the Pliocene.

The radiometric dating of the Yarden and Yarmuk Basalts, stratigraphically of late or post-Mindel age, indicates a minimum age of 0.66 Myr for the Mindel. This age limit provides an important link between the early Acheulian cultures of Europe and Africa and has been discussed in detail²⁴. Radiometric dates from Pleistocene deposits in Africa are fairly numerous, but in Europe there is almost no dateable Pleistocene material. Furthermore, climatic correlation between the European and African Pleistocene is poor, whereas the correlation between the European and Israeli Pleistocene seems well established¹⁷. Dating of the Israeli Pleistocene thus provides a sound basis for Pleistocene geochronology in Europe.

We thank Professor E. Jaeger and Dr J. C. Hunziker of the Mineralogisch-Petrographisch Institut, University of Bern, for facilities and assistance in the Ar-isotope determinations. We are grateful to I. Brenner, Geological Survey of Israel, for the specimens and unpublished field data, and to Dr J. A. Miller for reading the manuscript.

Vegetation classification by reference to strategies

J. P. Grime

Unit of Comparative Plant Ecology, Department of Botany, The University, Sheffield S10 2TN, UK

It is suggested that there are three major determinants of vegetation—competition, stress and disturbance—and that each has invoked a distinct strategy on the part of the flowering plant. A method is described whereby it is possible to distinguish types of herbaceous vegetation by reference to the relative importance of the three strategies in the genotypes of the component species.

THE electronic computer has been a mixed blessing to vegetation classification. On the one hand, it has facilitated the development of methods of numerical and multivariate analysis. On the other, it has contributed to the decline in confidence in

established methods but has yet to replace them with a new *lingua franca*. The resultant confusion in the field of vegetation classification is unfortunate in that it coincides with an unprecedented demand for standardised botanical information which can be readily interpreted and assimilated into plans to reclaim or manage the landscape.

This is not to argue for a return to the older methods of phytosociology which apart from their subjectivity are often difficult to apply in a world landscape experiencing increasingly diverse and disruptive interference by man. The current requirement is for methods of classification which can include recent or unstable vegetation, avoid unnecessary abstraction and provide data intelligible to nonspecialists. An approach to the classification of herbaceous vegetation has been made with these considerations in mind.

Fig. 1 A triangular model of herbaceous vegetation. *a*, Identification of the corners at which competition (C), stress (S) and disturbance (D) are exclusive determinants. *b-d*, Contours in percentage contribution of competition, stress and disturbance, respectively. *e*, Course of vegetation succession. The arrows correspond to lines of succession of low (L_1), moderate (L_2) and high (L_3) productivity. *f*, Interaction of competition, stress and disturbance. *g*, Location of selected habitat types.

Triangular ordination

The method depends upon the assertion that, basically, there are three determinants of herbaceous vegetation—competition, stress and disturbance—and that each has invoked a distinct strategy on the part of the flowering plant. The possibility arises therefore that an ordination of vegetation types can be based on measurements of the relative importance of the three strategies among the component species. More specifically, it is suggested that the spectrum of herbaceous vegetation types may be accommodated in a model (Fig. 1*a*) consisting of an equilateral triangle in the corners of which the relative importance of competition (C), stress (S) and disturbance (D) reach their respective maxima. In Fig. 1*b-d*, the gradients in relative importance of each of the three determinants are indicated by means of contours and in Fig. 1*f* the interactions between competition, stress and disturbance are summarised. Figure 1*g* illustrates the predicted location of selected habitat types within the triangle. The triangular model also appears to incorporate some of the dynamic features of herbaceous vegetation. The course of succession (Fig. 1*e*) is from the right-hand corner of the triangle towards the opposite side which constitutes the interface with woody vegetation. Increase in the angle of elevation of the line of succession (L_1 – L_3) above the horizontal is associated with a progressive increase in productivity. Species density (number of species per unit area) would be expected to show a progressive decline towards the apex as a result of competitive exclusion.

To derive from this model a practical method of ordination, the minimum requirement is to find measurable attributes of the flowering plant which vary in accordance with any two of the three sets of contours in Fig. 1*b-d*. To explore the possible means by which this requirement may be fulfilled it is necessary to consider the essential nature of competition, stress and disturbance and the strategies which they seem to have invoked.

Competition, stress and disturbance

Competition may be defined as the attempt by neighbouring plants to utilise the same units of light, water, mineral nutrients or space¹. By definition, therefore, competition exerts its maximum impact as a determinant of vegetation in circumstances where the competition is resolved perhaps even to the extent that the habitat is occupied by one species, possibly one individual plant. Stress and disturbance together comprise those phenomena which prevent the resolution of competition. At moderate intensities this intervention has the effect of creating spatial or temporal niches; at their most severe both stress and disturbance may so suppress plant development that individual plants scarcely impinge on each other and competition is occluded. The difference between stress and disturbance lies in the fact that whilst both inhibit the development of a large standing crop the former does so by restricting primary production, the latter by damage to the vegetation. Whereas stress is usually imposed by the physical environment (shortages of light, water, mineral nutrients, suboptimal temperatures, soil and toxins), disturbance arises from the activities of grazing animals, pathogens, man (trampling, mowing and ploughing) and from physical phenomena such as soil erosion. The same environmental factor, drought for example, may cause both stress and disturbance. In certain situations it is difficult to distinguish between competition and stress. In particular, problems of definition arise where herbaceous vegetation derives shade or phytotoxins from a remote tree canopy.

Three strategies

Many plant attributes have been implicated in adaptations to particular forms of competition, stress or disturbance. Here attention is focused on general characteristics of the competitive, stress-tolerant and ruderal strategies.

The competitive strategy. From both field and laboratory investigations of competition²⁻¹⁵, it seems that a number of plant attributes are conducive to the efficient capture and utilisation of light, water, mineral nutrients and space. These include an elevated leaf canopy, the capacity for extensive lateral spread both above and below ground and the tendency to accumulate a thick layer of litter on the ground surface, all characteristics which are especially prominent in herbaceous species such as *Pteridium aquilinum* and *Epilobium hirsutum*, which frequently occupy extensive areas of vegetation to the virtual exclusion of

other species. The ability of these three attributes to distinguish the competitive strategy is suggested by their very low incidence in environments subjected either to severe stress or to continuous disturbance¹⁶.

The stress tolerant strategy. In addition to small stature, a general characteristic of herbaceous plants in environments experiencing continuous and severe stress is a low potential relative growth rate¹⁷. This generalisation appears to hold for a wide variety of stresses including those associated with nutrient deficiencies on basic and acidic soils¹⁸⁻²³, shading^{24,25} and

Fig. 2 A triangular ordination of herbaceous species. ○, Annuals; ●, perennials (including biennials). The competitive index (CI) was calculated from the formula $CI = (a + b + c)/2$ where a , estimated maximum height of leaf canopy (1, < 12 cm; 2, 12–25 cm; 3, 25–37 cm; 4, 37–50 cm; 5, 50–62 cm; 6, 62–75 cm; 7, 75–87 cm; 8, 87–100 cm; 9, 100–112 cm; 10, > 112 cm); b , lateral spread (0, small therophytes; 1, robust therophytes; 2, perennials with compact unbranched rhizome or forming small (< 10 cm diameter) tussock; 3, perennials with rhizomatous system or tussock attaining diameter 10–25 cm; 4, perennials attaining diameter 26–100 cm; 5, perennials attaining diameter > 100 cm); c , estimated maximum accumulation of persistent litter (0, none; 1, thin, discontinuous cover; 2, thin, continuous cover; 3, up to 1 cm depth; 4, up to 5 cm depth; 5, > 5 cm depth).

Key to species: The value in brackets refers to the 95% confidence limit for R_{max} .

desiccation²³. In marked contrast, both the competitive and the ruderal strategies are associated with high potential relative growth rates^{23, 26, 27}.

The ruderal strategy. The majority of herbaceous species in highly disturbed habitats are annuals or short-lived perennials. A result of disturbance is the release of space and relief from stress and competition. It is not surprising, therefore, to find that a characteristic of many ruderals is the capacity for rapid seedling establishment and growth²³. A related feature is the tendency for a high proportion of the photosynthate to be directed into seeds and, under conditions of stress, for seed production to be maintained at the expense of vegetative growth^{28, 29}.

Ordination of species

To test the practical value of ordination by strategy, tests were carried out using data from an unpublished survey of the vegetation of the Sheffield region. As a first step, a triangular ordination was carried out on 100 herbaceous plants prominent in the data. One axis in the ordination was designed to correspond to the relative importance of the competitive strategy and was a numerical index based upon estimates of the maxima in height of canopy, lateral spread and litter accumulation derived from the field observations of Dr J. G. Hodgson and myself. The results of numerous investigations (for example refs 5–8, 11 and 13) suggest that in a majority of competitive species height of canopy is of greatest importance. For the purposes of this investigation, therefore, the maximum possible score for height of canopy was arranged to be twice that allowed for either lateral spread or litter accumulation (legend of Fig. 2). The competitive index used here differs from a predecessor¹⁶ both in the introduction of a weighting system and in the fact that relative growth rate is not incorporated. The second axis,

on a log scale, referred to stress tolerance and was R_{max} , the maximum relative growth rate of the species recorded during the period 2–5 weeks after germination in a standardised, productive growth-room environment²³. The values of R_{max} should be regarded as first estimates and may be subject to revision as data become available for other seed sources and conditions of growth.

In view of the provisional nature of the data, it is reassuring to find that the majority of the species fall within the triangle (Fig. 2) and, with certain exceptions, for example, *Origanum vulgare*, *Scabiosa columbaria* and *Tussilago farfara*, lie in close proximity to species with which they have strong ecological affinities. The left-hand corner is occupied by species tolerant of desiccation, for example *Sedum acre*, or shade, for example *Sanicula europaea*, or frequent in nutrient-deficient habitats whether acidic (*Deschampsia flexuosa*, *Nardus stricta*), calcareous (*Helictotrichon pratense*, *Sesleria albicans*) or associated with a wider range in soil pH (*Sieglingia decumbens*, *Viola riviniana*). Annual plants are concentrated in the 'ruderal corner' and show a significant ($P < 0.001$) and anticipated³⁰ rise in seed weight with increasing competitive index. Species of productive, derelict habitats occur towards the apex of the triangle. The unique position in the ordination of *Urtica dioica* is due to the unusually rapid growth rate of the species and is consistent with the sensitivity of the species to mineral-nutritional stress^{21, 23, 31}. The location of the winter annuals *Aira praecox*, *Veronica arvensis*, *Arenaria serpyllifolia* and *Draba muralis* coincides with that predicted for disturbed, unproductive habitats (Fig. 1g) and is quite distinct from that of the perennial plants such as *Festuca ovina* and *Koeleria cristata*, with which the annuals occur on limestone outcrops. This suggests that in such habitats the patches of bare soil occupied by the annuals constitute a distinct spatial and temporal niche.

Fig. 4 Pattern of species density (number of species m^{-2}) obtained by ordination of 925 samples of herbaceous vegetation from a wide range of habitats. Axes are the same as in Fig. 3. In each cell the uppermost values are the mean and 95% confidence limit for samples from sites with a surface soil pH > 4.0. The lower values refer to samples of pH < 4.1.

* Cells containing less than five samples.

Ordination of vegetation samples

The second step in evaluating the approach was to ordinate vegetation samples from a wide variety of habitats. The axes were based on mean values for individual quadrats of both the competitive index and R_{max} , with R_{max} again plotted on a logarithmic scale. In the case of the competitive index, the values for each species which contributed towards the mean for the quadrat were weighted according to the relative importance of the species in the m^2 sample. An identical system of weighting was applied in the calculation of mean R_{max} for the quadrat although here data were necessarily restricted to those species for which growth analyses had been carried out (> 50%) and including the more frequent species in the majority of samples). A selection of the ordinations is presented in Fig. 3. The various types of vegetation occupy positions in quite close agreement with those predicted in Fig. 1g. The figures illustrate the tendency of samples from stressed habitats (a, b, c), disturbed environments (j, k) and semiderelict but productive sites (g, h, i) to extend into respective corners of the triangle. Vegetation types experiencing a moderate intensity of orderly disturbance (d, e, f) tend to occupy compact areas in the centre of the diagram. By contrast, samples from spoiled land (l-o) show an attenuated distribution which seems to represent the course of vegetation succession in these new habitats (compare Fig. 1e).

Figure 4 illustrates the pattern of species density which was obtained by pooling data from 25 ordinations (925 samples). When 103 samples from extremely acidic soils (surface soil pH < 4.1) are discounted the predicted decline in species density, towards the apex of the triangle, is apparent. The fall in species density in the lowest rank of cells is probably related to the scarcity of species adapted to extremes of stress and disturbance¹⁶.

Future developments

The consistent patterns evident in Fig. 3 are encouraging, particularly in view of the fact that the samples in each ordination have been drawn from localities scattered over a wide geo-

graphical area. However, there is obvious scope for refinement of the method. There is a need for more accurate estimations of R_{max} and for an assessment of the extent to which this attribute and others used in the ordination is subject to intraspecific variation. It is also necessary to evaluate alternative criteria with respect to both the competitive and the stress-resistant strategies. In addition, the possibility of a 'ruderal axis', perhaps related to 'reproductive effort'³² remains to be examined.

None of the species in Fig. 2 occurs within the two areas of the triangle corresponding to extreme competition or severe stress. This may be due to deficiencies in the axes or in the data. An alternative explanation is that it is necessary to explore beyond a temperate herbaceous flora in order to find the necessary conjunctions of R_{max} and competitive index.

The value of this triangular ordination to vegetation management lies at present in the ability to detect the intensity of competition and stress and to predict the intensity of disturbance at particular sites. If the approach is to be put to maximum use, however, it must be complemented by techniques which identify particular forms of competition, stress and disturbance.

I thank Dr J. G. Hodgson and Dr R. Hunt for their helpful criticism of the manuscript and for their permission to draw upon the results of unpublished collaborative projects, and also A. V. Curtis and A. M. Neal for their participation in field and laboratory work. This research was supported by the Natural Environment Research Council.

Computer-aided reconstruction of immature brain cells with highly irregular shapes from serial electron microscopic montages gives three-dimensional images and quantitative data on surface areas and volumes, providing new classes of data on cell behaviour during development.

KNOWLEDGE of structural relationships between cells in the central nervous system has reached a level of precision that requires efficient high resolution methods of quantitative three dimensional analysis. The classic Golgi method^{1,2} provides a blackened image of the complete silhouette of individual cells against an almost colourless background, and steps have been taken to obtain quantitative cytological data with computer aid³. But this method lacks adequate resolution and usually does not facilitate visualisation of relationships between contiguous cells. The transmission electron microscope provides appropriate resolution and facilitates visualisation of the profiles of cell bodies and processes, and their relationships with other cells in a given field of view. Preparation of several hundred consecutive serial sections is now feasible and computer-aided reconstruction methods have been applied to electron microscopic analysis of the organisation of invertebrate neural tissue (refs 4 and 5 and personal communication from S. Brenner). We describe here the application of a quantitative computer-aided method to the analysis of cell shapes,

volumes and surface areas as visualised in electron micrographs of a sector of foetal monkey cerebrum.

A 58-d embryo was removed from an anaesthetised *Macacus rhesus* monkey by hysterotomy and perfused through the circulatory system with a mixture of 1% formaldehyde and 1.25% glutaraldehyde in 0.1 M phosphate buffer⁶. Blocks of tissue 1×1×0.5 mm were postfixed in OsO₄, stained with uranyl acetate, dehydrated and embedded in Maraglas. Precisely oriented transverse sections 1 μm thick were cut from a sector of cerebral wall approximately at the border of the occipital and temporal lobes (Fig. 1a). The block was remounted and trimmed to a rhomboid shape, yielding a final block face that extended from the ventricular zone to the base of the cortical plate (Fig. 1b) and included a sector of sub-ventricular zone about 100 μm thick and intermediate zone 300 μm thick (neuroembryological terminology recommended by Boulder Committee⁷). A set of 170 consecutive serial sections, each about 80 nm thick, was mounted on Formvar film on one-hole (1×2 mm) grids and stained with uranyl acetate and lead citrate. From every third section, 16–20 overlapping fields were photographed at ×2,800 with a Hitachi electron microscope and montages were prepared of prints at a final magnification of ×8,400. Selected cells and their nuclei were outlined on transparent acetate sheets, and minor adjustments in alignments were made by reference to nearby transversely cut cell processes and capillaries. Registration marks were placed on each transparency for alignment

Fig. 1a Outline of a coronal section across the occipital lobe of a 58-d-old monkey embryo. The cerebral ventricle (CV) is relatively large at this stage and the lateral wall (L) is much thicker than the medial wall (M) on which the incipient calcarine fissure is slightly indented. The shaded area between the arrowheads indicates the position of the block of tissue that was processed for electron microscopy. **b**, Drawing of a 1 μ m thick, toluidine blue-stained section across the entire area shaded in (a). The cerebral wall from the ventricular surface at the bottom to the external surface at the top of the drawing consists of ventricular zone (VZ), subventricular zone (SV), intermediate zone (IZ) and cortical plate (CP). The area outlined by the rhomboid was cut serially for electron microscopy. Overlapping squares represent individual fields photographed for the reconstruction on photomontages. Arrows A to F point to the positions of six cells reconstructed in this study.

purposes. A representative electron microscopic field from which cell outlines were traced is illustrated in Fig. 2a. Considerable human judgement is involved in the choice of valid cell contours, and we thought it not worthwhile to attempt to automate this step.

Computer analysis

The cell and nuclear contours on the serial section transparencies were digitised as follows. The registration marks on successive transparencies were carefully aligned with pre-marked registration indicators on the digitiser to establish the x and y axes, and the height of the serial section above a reference level was dialled into the digitiser to provide elevation information (z axis). In the case of cells with complex shapes, more than one contour sometimes appeared on a transparency. Each contour on the transparency was traced with the cursor of the digitiser and the coordinates of selected points were recorded by the operator. The x-y coordinates of each point, the z coordinate of the transparency, and an identifying integer were transferred automatically to punched cards. Each closed membrane contour constituted a data set. Scaling information was recorded separately and used to convert the x-y-z data into absolute physical units.

The basic software for processing was prepared for an IBM 360/75 computer. The software reads the individual sets of data into memory, recognises multiple contours on a level, scales the data and computes the volume and surface area of each cell and nucleus as represented by the digital images. Registration is not necessary to obtain volume and surface area, but is necessary for graphic presentation.

Graphic software has also been written which gives the viewer the choice of observing the cell from any desired angle of rotation about the axis of the image (Fig. 2b-d). Standard Eulerian and projective transformations accomplish this efficiently. Presentation of the cell or nucleus as a three dimensional solid in space required the suppression of points hidden from the observer's eye. The requirement for a fixed number of points per contour is too strict a condition for the type of data considered⁸. A new method was developed which has no constraints on the number of points per contour or the number of contours per level. An arbitrary maximum can be set on the total number of points needed to specify the cell. The visibility algorithm depends only on the property of whether a point falls inside or outside the contour of visible points which preceded it. Visibility is determined data set by data set beginning with the first contour on the level closest to the observer and proceeding to the last on the contour furthest away.

Fig. 2a Electron micrograph of cell C in serial section no. 83. Although the processes of all cells are in close apposition, it is relatively easy for the human observer to trace the irregular outline of a given cell. **b-d**, Cell C, as reconstructed from several fields, including that shown in (a). Only every ninth outline is represented, to make diagrams legible. In the three drawings, the cell is rotated on the axis running from pole to pole by 0°, 45° and 135°, respectively.

Considerable savings in computer time can be effected with a variation of the method. The intensity of each segment making up a contour is weighted according to its distance from the observer; nearer contours are reproduced in progressively thicker and darker lines, further ones are thinner and lighter (Fig. 2*b-d*). The effect achieved is similar to full hidden line suppression. To illustrate the savings achieved with this method, two trial cases each having 800 points of coordinate data representing 25 levels of contour data were processed using (1) full hidden line suppression, and (2) intensity weighting. Full hidden line suppression required 2.5 min of Central Processing Unit time on an IBM 360/75 computer compared with 0.5 min for intensity weighting. Therefore we used the latter mode of presentation in the preparation of the computer graphics presented here.

Three dimensional reconstruction

Of 24 cells reconstructed, six were examined in detail: two in the subventricular zone (Fig. 1*b*, cells A and B), two in the inner part of the intermediate zone (cells C and D) and two in the outer part of the intermediate zone (cells E and F).

volume though not in shape (Fig. 3*b, d* and *i-l*). The nucleocytoplasmic volume ratios and the cell surface area-volume ratios express numerically the relatively round compared with the elongated configurations of the cells (Table 1). The most interesting quantitative feature is the striking difference in cytoplasmic volume between cells E and F, which migrated the greatest distance, and cells C and D, which migrated less. If these four cells belong to the same postmitotic neuronal class, the data suggest considerable cell growth during migration. Alternative possibilities are that the cells are not statistically different in size or that cells C and D are smaller because they belong to a different population, destined for a different cortical layer¹⁴. Another important quantitative feature is the increase in surface area during elongation of the cells to bipolar shapes (compare cells A and B with C and D in Table 1) and a possible further increase in surface area as cells approach the cortical plate (cells E and F), an indication of net synthesis of cell membrane during migration. When more significant statistical samples are obtained new concepts may well emerge concerning the mechanisms and significance of cell movement in the developing central nervous system.

Figures 3*e-h* show that at the stage of cortical development under study, every migrating neurone examined is in contact with radially oriented fibres (compare refs 6 and 10). The leading processes of the migrating neurones have complex

Table 1 Quantitative cellular data

Cell	Surface area (μm^2)	Total volume (μm^3)	Ratio: area volume	Cytoplasmic volume (μm^3)	Nuclear volume (μm^3)	Ratio: nuclear volume cytoplasmic volume

From their positions and morphology as represented in random sections, we had suspected that cells A and B were subventricular (neuronal or glial precursors, possibly still proliferating), while cells C-F were postmitotic young neurones whose positions along the migration trajectory to the cortical plate should, in a general way, reflect their ages^{6,9}. Three-dimensional computer displays of the contours of cell C reconstructed from many sections, and viewed from three different angles are illustrated in Fig. 2*b-d*.

Drawings of all six cells, their nuclei and some contiguous bundles of fibres of relatively small calibre are shown in Fig. 3. These were made manually to scale directly from the tracings, with frequent reference to the original electron micrographs. Comparison of Figs 2*d* and 3*e* shows that the manual and computer reconstructions give similar results.

Volumes and surface areas

The computerised method of cell reconstruction reported here represents a departure from the slower and more laborious wax plate procedure adopted in earlier electron microscopic studies^{9,12,13}. It requires less time and labour, and provides a set of quantitative data of biological interest (Table 1). Although the sample of data is small, it suggests certain trends. Of the two subventricular cells, B has a much larger nucleus, which seems to be in a different class from those of the other cells, and we suspect both from this measurement and its electron microscopic appearance that cell B has just entered mitosis. The other nuclei resemble one another in

forms, reminiscent of the appearance of cells observed directly during migration in tissue culture¹¹. Leading processes commonly extend along more than one radial fibre (Fig. 3*e* and *h*). They terminate within the intermediate zone and in the sample of 24 cells, they have not been seen to extend into the cortical plate or through it to the external surface of the cerebrum. The cell shape (Fig. 3*g*) suggests that the leading processes are plastic, some withdrawn and others extended further as the cell migrates toward the cortex; if the number and form of the leading processes were fixed, this cell would be unable to advance beyond the fibre bundle that lies across the migration path and passes in front of one apical process and behind the other. Trailing processes were followed in some instances to their tapered terminations (for example, cell E) or to a point where they pass from the serially cut tissue (for example, cell C). It is also noteworthy that the rounded subventricular cells A and B, which do not seem to be migrating, likewise contact radial fibres (Fig. 3*a* and *c*). Such cells were not examined in the earlier studies^{6,10}, and it is not clear from this small sample whether or not subventricular cells usually relate to radial fibres.

Further prospects

Investigators may have some difficulty in estimating their computer requirements in relation to the complexity of their biological data. On the one hand, a mini-computer such as the PDP-11/05 with graphic accessories would permit the recording and display of a set of serial section contours but would allow only limited image rotation or data storage for large complex cells. On the other hand, a computer of the

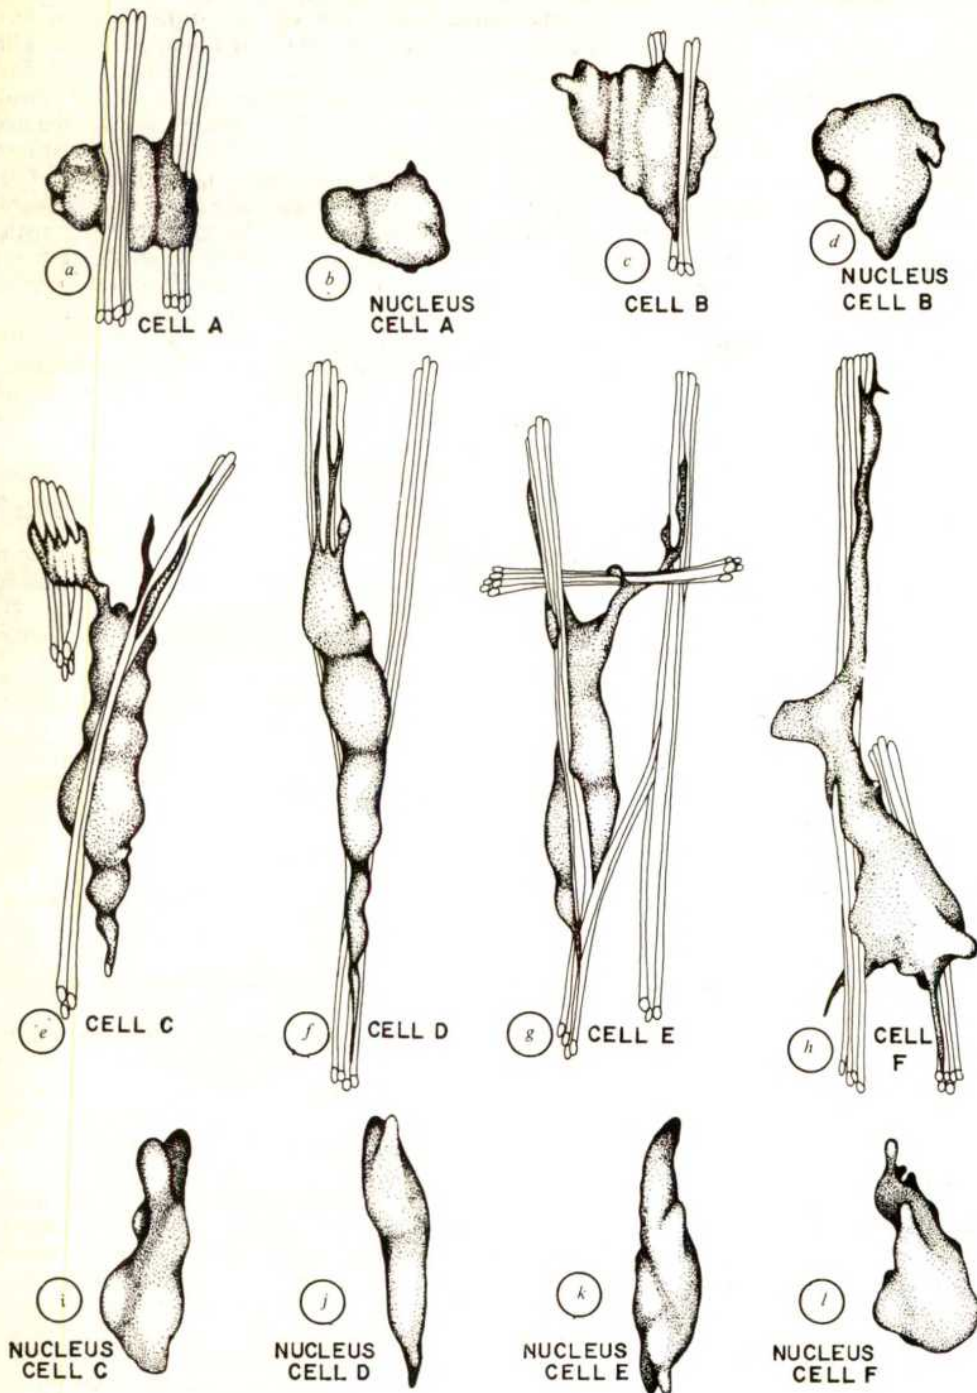

Fig. 3 a, c, e-h represent reconstructions of cells A to F respectively. Cells were drawn with the aid of superimposed outlines of cell profiles in serial sections at different levels traced onto transparent Mylar sheets. Some of the fibres which lie in contiguity with the migrating cells were also traced and reconstructed but most of the neighbouring cells and processes were omitted. b, d and i-l represent similarly reconstructed nuclei of cells A to F, respectively.

- IBM 360/75 type which we used has a larger capacity than we needed. Its greater storage capability will be necessary, however, to handle more complex issues such as spatial relationships among several cells that are changing their positions relative to one another in the developing brain. It will be needed also for analysis of the shapes and relationships of mature neurones, particularly for quantitative plotting and three dimensional display of synaptic inputs.

LETTERS TO NATURE

PHYSICAL SCIENCES

Was Jupiter the protosun's core?

THE differences between Jupiter and conventional stars are apparently due solely to its small mass. Therefore in looking for possible means of formation of the Solar System it is natural to attempt to establish the origin of the Jupiter-Sun binary system. The other planets could be just a by-product of the evolution of this system.

I shall start from the hypothesis that the close binaries form as a result of the rotational-exchange instability of the protostar (my unpublished work). This hypothesis can be formulated as follows.

Immediately after the collapse of the prestellar cloud, convection begins in the protostar formed¹. The initial differential rotation is replaced in a zone of convective mixing by uniform rotation (mixing can be caused by an instability of the differential rotation proper during the onset of quasihydrostatic equilibrium in the protostar). Because of the transfer of angular momentum, the centrifugal force can exceed the gravitational force in the outer layers. These layers will then become separated, forming a massive ring rotating around the protostar. A fast (adiabatic) loss of mass from the convective zone (the politrope index being 1.5) produces an increase in its size². As a result, the transfer of mass on to the ring, just as in the later stages of close binary evolution, proceeds on a 'dynamic' time-scale until the convective envelope is totally lost³. The ring is unstable, breaking up and collapsing into one or several bodies at some stage.

In this way a multiple system is formed, and the mass ratio of its components should thus depend on that of the convective zone and of the stable core in the protostar. The fraction of the total mass involved in convection depends critically on the density of the prestellar cloud, but it should generally be larger the smaller is the mass of the protostar⁴. The accounts for the observed decrease (ref. 5 and my unpublished work) of the number of binaries with a short period ($P \lesssim 5-7$ d) and a small component mass ratio ($q < 0.8$) as one goes from B to F stars. Apparently the masses of the convective envelope and of the stable core in protostars forming close binaries with F components are, on the average, the same. The systems here have a $q \approx 1$.

With less massive protostars, systems with $q < 1$ should appear again (my unpublished work) but here the more massive component is formed by the lost matter. The loss of a larger mass releases a larger angular momentum J contained in the protostar. The system period increases at a fixed total mass, $P \propto J^3(1+q)^6 q^{-3}$ becoming longer than $5-7^6$. Such systems are difficult to find.

When convection extends throughout the protostar, practically all the initial mass should become transferred on to the object formed by ring condensation.

Indeed, convection penetrates into the star from outside, so that fast mass transfer begins, as a rule, before convection has reached the centre. Matter involved in convection is lost continuously so that the protostar retains only a small fraction of its initial mass at the time when the centre regains radiative stability after becoming convective.

The major factor determining the completion of transfer

is apparently the cooling of the protostar remnant caused by its fast expansion and radiation of energy. Nonvolatile components condense, forming in the protostar remnant a rocky core (and probably bodies orbiting in the outer rarified zone of the remnant).

Thus the above process of breakup of the protostar and of the mass exchange between its fragments results in the formation of a fairly wide system consisting of a newly formed massive star and the remnant of the protostar, its mass being much less than the initial mass. We now have a star with a satellite, that is with a planet.

Turning now to the Solar System, it is natural to assume Jupiter to be such a remnant of a protostar. This provides an easy explanation for the origin of the terrestrial planets and for their great difference from the massive Jupiter. These planets condensed and acquired angular momentum from the matter streaming from Jupiter—the protostar (the primary component)—to its satellite—the Sun (the secondary component).

This matter carries some angular momentum and therefore forms a rotating disk around the secondary. Keplerian motion in the disk is upset by friction transferring angular momentum to the disk's periphery. From here, the matter is thrown out by centrifugal force which carries away the momentum excess. The matter from the disk's interior is deposited on to the secondary⁶.

The gas dynamics of such a rotating disk have not been studied in detail but it is evident that the physical parameters should vary over a wide range, from thousands of K and tens and more atmospheres in the stream flowing from the primary⁷ and in shock waves generated by its motion, to hundreds of K and fractions of an atmosphere far away from both components. Within such a wide range one can easily envisage the realisation of the conditions necessary for the production of some chemical compounds and of their condensates which are needed for the formation of the terrestrial planets^{8,9}.

As for the planets beyond Jupiter, they could have formed from fragments of already sufficiently dense matter which remained from (or was thrown out in) the collapse of the ring separated from the protosun. The majority of the fragments coalesced and/or dispersed in collisions with one another and the parent bodies. The remaining fragments could have acquired arbitrary orientation of axial rotation (Uranus).

Afterwards, when the disk rotated around the Sun giving birth to the terrestrial planets, the loss of excess angular momentum from it resulted in the matter concentrating beyond the Jupiter-Sun system. Part of the matter was captured by the massive fragments-planets, while another part (just as in the inner disk but at a lower temperature) could condense to form planets similar in many respects to those of the Earth group, as well as comets (Oort's cloud).

The reasons for the slow rotation of the Sun, just as in the case of close binary stellar systems (my unpublished work), should be looked for in the effect of the rotation of the primary on the magnitude (and even sign) of the angular momentum of matter streaming away from it¹⁰. If the equatorial velocity of the primary greatly exceeds the

orbital velocity then the streaming matter will not form a disk, and the secondary (the Sun) will increase in mass with almost no increase of the momentum of its axial rotation.

Gamma rays from black holes

As a result of electron ion decoupling, the compression of interstellar matter falling on to an isolated black hole results in ion temperatures greater than 100 MeV as the matter approaches the Schwarzschild radius. Here, experimental pion production cross sections are used to calculate the rate of production of γ rays from this hot gas. A characteristic γ -ray spectrum is produced, which peaks at 18 MeV regardless of the mass of the black hole or the interstellar density.

Matter accreting on to a black hole may be heated to very high temperatures and radiate γ rays^{1,2}. The accretion of matter onto a black hole can be treated as a hydrodynamic flow if a weak magnetic field is carried with the accreting gas^{1,3}. In the hydrodynamic model the accreting gas is rapidly compressed as it falls inwards, causing a significant fraction of the gravitational potential energy to be converted into thermal energy. Moreover, if the mass of the black hole is not too large ($\leq 10^4 M_\odot$) the accreting gas radiates away only a small fraction of the available thermal energy^{1,2}, so the compression of the accreting gas will be very nearly adiabatic. The temperature of the accreting gas at a distance r from the centre of the black hole is given by:

$$\theta(r) \approx 0.5 \theta_0 (r_1/r)^{3(\gamma-1)/2} \quad (1)$$

where γ is the average adiabatic index, r_1 is the distance at which the gas begins to fall inwards, and θ_0 is the temperature of the gas as it begins to fall. The distance r_1 will be given by⁴:

$$r_1 = (2GM/c^2) (m_p c^2 / \gamma \theta_0) \quad (2)$$

where M is the mass of the black hole and m_p is the proton mass (assuming that the interstellar medium is predominantly hydrogen).

The temperature of the accreting gas near the gravitational radius, $r_g = 2GM/c^2$, depends markedly on whether the gas is ionised when it begins to fall inwards. If the gas is not initially ionised, then the temperature of the accreting gas does not get hotter than about 10^9 K (ref. 2). The gas near a black hole may, however, be ionised with $\theta_0 \sim 1$ eV (ref. 3), in which case (using a one-temperature approximation and assuming an average adiabatic index of 13/9 when the electrons become relativistic) there is a gas temperature of 10^{11} K near the Schwarzschild radius². The electron-ion coupling time, however, turns out to be much longer than the radial infall time so that it is more appropriate to use different temperatures and different adiabatic indices for the ions and electrons. As the ions are non-

relativistic at temperatures less than 100 MeV $\gamma = 5/3$ can be used, and the ion temperature is¹:

$$\theta_i(r) \approx 0.3 m_p c^2 (r_g/r) \quad (3)$$

Thus, the ion temperature exceeds 100 MeV as the accreting gas approaches the gravitational radius. The ion density is¹:

$$n(r) = 6.10^{12} n_0 (r_1/r)^{3/2} \quad (4)$$

Considering the change in adiabatic index for the relativistic electrons, they approach a temperature of about 10 MeV near the gravitational radius if $M \leq 10^4 M_\odot$. The ion-electron Coulomb coupling time for $r < 100 r_g$ is $> 10^6$ s, which is far longer than the radial infall time $\lesssim 10^{-3}$ s, so the ions and electrons are indeed uncoupled. This is not altered by the presence of a turbulent magnetic field¹ if there is approximate equipartition of the magnetic field energy and the gas kinetic energy. The turbulent magnetic field tends to heat the ions at the expense of infall kinetic energy. The validity of the hydrodynamic approximation depends only on the smallness of the proton cyclotron radius relative to scales of interest.

At temperatures in excess of 100 MeV proton-proton collisions result in copious pion production, and γ rays will be produced because of the decay $\pi^0 \rightarrow 2\gamma$. This process is the main contribution to the γ -ray luminosity of black holes.

The rate of π^0 production in a hot gas with proper density n is $(n^2/2) \langle \pi^0 \rangle \bar{\sigma} \bar{v}(\theta)$; where $\langle \pi^0 \rangle$ is the average number of π^0 's produced per collision, and σ is the pion production cross section. The quantity $\bar{\sigma} \bar{v}(\theta)$ is related to the laboratory pion production cross section $\sigma(E)$ by:

$$\bar{\sigma} \bar{v}(\theta) = \iint \sigma(E_L) v_L f(\mathbf{p}_1) f(\mathbf{p}_2) d\mathbf{p}_1 d\mathbf{p}_2 \quad (5)$$

where v_L is the laboratory velocity and f is the thermal distribution. Numerical evaluation of equation (5), using the experimental pion production cross sections⁵, and a relativistic Maxwell distribution, provides a curve of $\bar{\sigma} \bar{v}$ against θ (Fig. 1). Knowing the ion temperature and density as a function of r the production of pion γ rays can be calculated as a function

Fig. 1 Relativistic thermal average of $\sigma \bar{v}$, where σ is the cross section for the total pion production.

Fig. 2 Differential γ -ray spectrum from a $10 M_{\odot}$ black hole in a region of density $= 1 \text{ cm}^{-3}$, and $\theta_0 = 1 \text{ eV}$.

of r . The total rate of emission of γ rays resulting from spherical accretion is:

$$\dot{N}_{\gamma} = \int_{r_g}^{\infty} \langle \pi^0 \rangle n^2 \bar{\sigma} v(\theta) [1 + (\cos \psi - V/c)/(1 - V/c \cos \psi)] 2\pi r^2 dr \quad (6)$$

where V is the radial infall velocity and ψ is the half angle of the radiation 'escape cone'. Numerical evaluation of the right side of equation (6), using the values of $\bar{\sigma} v(\theta)$ shown in Fig. 1 and equation (3) and (4) gives:

$$\dot{N}_{\gamma} \approx 3 \times 10^{26} (M/M_{\odot})^3 (1 \text{ eV}/\theta_0)^3 n_0^2 \text{ s}^{-1} \quad (7)$$

These γ rays have energies of the order of 20 MeV, so that the γ ray luminosity resulting from spherical accretion is:

$$L_{\gamma} \approx 10^{22} (M/M_{\odot})^3 (1 \text{ eV}/\theta_0)^3 n_0^2 \text{ erg s}^{-1} \quad (8)$$

This is larger than the γ -ray luminosity resulting from bremsstrahlung emission², but it is small compared to the total luminosity of the black hole, which results from the synchrotron radiation of visible light¹. It may be larger than indicated in equation (8) if matter is falling onto an isolated rotating black hole because of the accumulation of matter in orbits near r_g . Accreting disk models in binary systems⁶, have a much lower luminosity γ -ray because the accreted material has time to radiate a significant fraction of its energy, thus invalidating the adiabatic approximation.

The spectrum of γ rays emerging from the accreting gas will be determined by: the energy spectrum of the π^0 's as observed by a comoving observer; the Doppler shift resulting from the radial infall of the gas; and the gravitational redshift. More than half of the γ -ray emission comes from the region $r_g < r < 2r_g$, so the gravitational red shift is an important effect.

The γ -ray spectrum in a comoving frame which results from the energy spectrum of the π^0 's, can be calculated to sufficient accuracy by noting that for laboratory energies of less than 4 GeV almost all pion production occurs through an $N^*(1236)$ intermediate state. Thus, in order to calculate the γ -ray spectrum in a comoving frame only the γ -ray spectrum in the rest frame of an $N^*(1236)$ need be known. It can be obtained⁷ by convoluting the spectrum in the N^* rest frame with the relativistic thermal Doppler spectrum $\phi(\omega) = (2\omega)^{-1} \gamma(\omega) \exp[(m_{N^*} c^2/\theta_1) \gamma(\omega)]/K_1(m_{N^*} c^2/\theta_1)$; where $\gamma(\omega) = (\omega/\omega_0 + \omega_0/\omega)/2$ and ω_0 is the γ -ray energy in the N^* rest frame. If ω_1 is the γ -ray energy in the comoving frame then the frequency measured by a distant observer is:

$$\omega_{obs} = \omega_1 [(1 - v/c)/(1 + v/c)]^{1/2} (1 - r_g/r)^{1/2} \quad (9)$$

(We have neglected the angular dependence of the Doppler

shift because the escape cone light of sight is nearly radial when the infall velocity is largest.) The spectrum obtained by integrating the contributions from all radii has a width of ~ 80 MeV, and falls off approximately as E^{-3} for $100 \text{ MeV} < E < 300 \text{ MeV}$ (Fig. 2).

The spectrum (Fig. 2) is universal in the sense that its shape is independent of the mass of the black hole or the interstellar density. Thus, if many black holes are present in the Universe some kind of anomalous feature could be expected in the γ -ray background in the neighbourhood of 10 MeV. The spectrum from black holes in our Galaxy would have a peak at 18 MeV; the spectrum from black holes in other galaxies would peak below 18 MeV because of cosmological redshift which lowers the peak in the 'background' spectrum to ~ 10 MeV. An anomalous feature in the γ -ray background at about 10 MeV has, in fact, been reported at a level of about $10^{-4} \text{ } \gamma \text{ s cm}^{-2} \text{ sr}^{-1} \text{ MeV}^{-1}$ (refs 8 and 9).

If this anomaly results from isotropic emission from external galaxies with $30 M_{\odot}$ black holes, then about 10^{10} black holes per galaxy are required, assuming equation (7) for the γ -ray luminosity and $n_0 = 100 \text{ cm}^{-3}$. As mentioned, higher γ -ray luminosities may occur, thereby decreasing the number of black holes required. In our Galaxy, upper limits on the emission above 15 MeV from the galactic centre¹⁰ indicate that as many as 10^7 $30 M_{\odot}$ black holes may be in that vicinity if $n_0 = 100 \text{ cm}^{-3}$.

Do black holes really explode?

THE creation of particles out of the vacuum will occur in regions of space-time where the metric is changing rapidly. Theoretical discussions of this process encounter some interpretational difficulties, however, because the concept of 'particle' is only well understood in Minkowski space. Nevertheless, in some simple cases, for example with the metric of homogeneous cosmologies, or of black holes of the Kerr and Schwarzschild type, the existence of a global timelike Killing vector allows a very plausible extension of the Minkowski space definition of particle. A number of exact results may then be proved. One of these results (ref. 1, and C. J. Isham and J. G. Taylor, personal communication) states that there is no creation of massless particles in the exterior region of a Schwarzschild black hole, which is the static end state reached as a result of spherically symmetric gravitational collapse. This result is not valid for a Kerr (rotating) black hole for essentially classical reasons².

Nevertheless, during the collapse of a spherically symmetric object, the metric near the surface will be changing rapidly on a time scale of $\tau \approx 10^{-5} (M/M_\odot)$ s, so that on general grounds the production of massless particles with energy of order \hbar/τ is expected. Many of these particles will escape from the surface of the object and reach distant observers. The energy removed in this way will slow up the collapse and may even prevent it completely, thus causing the collapsing object to 'explode' in a burst of radiation. Exact calculations of this explosion are not possible with present theory, which does not enable the back reaction of the particle creation on the metric (a quantum gravitational correction) to be evaluated. A rough idea may be obtained, however, by treating quantised fields in a given classical background metric, and estimating the amount of particle emission as the collapse proceeds.

If we assume that the production rate is more or less constant during the collapse, the surface will have a luminosity L_0 , but a distant observer will see a rapidly fading luminosity as the retreating surface falls towards the event horizon:

$$L(t) = L_0 \exp(-t/\tau) \quad (1)$$

Particle creation will only be important for objects with $M \ll M_\odot$, and it follows from equation (1) that in this case the radiation will be emitted in a flash with a duration of much less than a microsecond. The spectrum of radiation will be given (roughly) by the Fourier transform of equation (1), that is, proportional to $v/(v^2 + v_0^2)$ where $v_0 = (2\pi\tau)^{-1}$. This is peaked around $v = v_0$ so that a distant observer might approximate this spectrum with that of a blackbody with a Planck spectrum $v/[\exp(\hbar v/kT) - 1]$, corresponding to a temperature

$$T \approx \hbar v_0/k \approx 10^{-6} (M/M_\odot) \text{ K} \quad (2)$$

where k is Boltzmann's constant. This result has already been obtained in another way³.

Treating the collapsing object as a blackbody radiator with temperature T for the duration of the 'flash', the energy emitted per unit time will be about $A\sigma T^4$, where σ is Stefan's constant, and A the surface area, which will not be greatly different from that of a final black hole of the same mass, that is, $16\pi G^2 M^2/c^4$. Consequently, the total mass loss by the object as a result of massless particle emission will be in the region of

$$(16\pi M^2 \sigma) \times (\hbar v_0/k)^4 \approx \hbar c/MG \quad (3)$$

with a numerical coefficient on the right hand side involving only small powers of 10. This result may be written as a fractional mass loss

$$\Delta M/M \sim (\text{Compton wavelength of object/Planck length})^2.$$

Evidently, black hole explosions with $\Delta M \approx M$ will only occur for an object the Compton wavelength of which is comparable with the Planck length, that is for masses of about 10^{-4} g and densities of 10^{94} g cm⁻³. This is just the region where quantum gravitational effects also become important. Indeed, this result is not surprising because in order to reverse the collapse, the back reaction of the created particles on the dynamics of the collapse needs to be appreciable, and this can only occur when quantum corrections to gravity become important.

Equation (3) is confirmed by the detailed calculations of Zel'dovich and Starobinskii⁴, who have treated the problem of massless particle creation in the context of anisotropic cosmological models. They have verified the formula $\hbar/c^3 t^4$, originally deduced on dimensional grounds, for the energy density of created particles at a time t before collapse to a singularity. If a collapsing anisotropic single object is treated as a region of an anisotropic universe, this formula can be applied to obtain the total created particle energy-density over a time scale of order τ to obtain

$$(\hbar/c^3)\tau^{-4} \times (\text{volume object}) \sim \hbar c/MG$$

as before. Because of the additional tidal forces present in anisotropic collapse, spherically symmetric collapse would not be expected to lead to a greater particle production than this.

The conclusions of this simple treatment of particle production around collapsing objects seems to be in conflict with a recent result by Hawking⁵, who claims that black holes as large

as 10^6 gm would explode in massless radiation in about 0.1 s. Collapsing objects of this mass have an energy density only of the order 10^{-27} of that of quantum gravity fluctuations, so that this 'explosion' is more like a slow 'leak'. The e folding time for collapse is 10^{-29} s at this mass, so that Hawking's result implies that emission of massless particles continues to occur when the static limit of a Schwarzschild field is an exceedingly good approximation. It is not therefore clear what mechanism could be responsible for this emission (on the assumption of a reasonable definition of 'particle'). Any particles produced near the surface of a collapsing object will find it increasingly difficult to escape as the event horizon is approached. The last quantum ever able to reach a distant observer does so after an (asymptotic) time of only about 100 e folding times (10^{-27} s in this case)⁶. Hawking's result is, on the other hand, deduced on the assumption that the black-hole temperature given by equation (2) persists, unaffected by the collapse of the object, in the external asymptotic region, rather than fading out rapidly in accordance with equation (1). In our view it is a rather too literal interpretation of the concept of the 'temperature' of a black hole to apply it to emission processes in this way, and its use should be restricted to the discussion of absorption, as originally suggested by Bekenstein⁷.

Further simultaneous hard X-ray and optical observations of Sco X-1

THE optical and X-ray emissions from Sco X-1 are thought to come from a hot plasma as small as or smaller than a white dwarf¹, but the energy source and the time variations of the radiation are not understood.

In our 1971 observations we found a positive correlation between the optical luminosity and the intensity of hard X rays at the optically enhanced phase of Sco X-1 (refs 2 and 3). Although the optical enhancement seemed to be a flare, a rather poor time resolution of the photographic observation prevented us from identifying it for certain. During a balloon flight on April 16, 1972, an X-ray enhancement was observed simultaneously with an optical flare, the latter being verified by photoelectric observation. With the result of another balloon flight on April 19, 1972, the hard X-ray spectra at several different B magnitudes are available for the study of the correlation between X-ray and optical emissions.

The instruments essentially the same as the one in the previous flight³, were launched on April 16 and 19, 1972, from Hyderabad, India. The balloon floated at the atmospheric depth of 2.9 to 3.0 g cm⁻² for about 4 h in each case. One of the counters in the April 16 flight malfunctioned, and its data were discarded.

Table 1 Results for Sco X-1 in selected periods

Date	Time (UT)	m_B	X-ray intensity at 30 keV ($\text{keV cm}^{-2} \text{s}^{-1} \text{keV}^{-1}$)	Apparent* temperature	τ_{es}	Mass (10^{19}g)
May 1, 1971	2009–2018	12.6	0.060 ± 0.023	4.7 ± 0.7	8.6	1.7
May 1, 1971	2057–2106	12.4	0.12 ± 0.01	5.1 ± 0.3	9.9	2.0
April 16, 1972	2217–2225	12.5	0.12 ± 0.01	5.1 ± 0.4	10.0	1.8
April 16, 1972	2241–2246	12.3	0.20 ± 0.02	5.3 ± 0.5	10.7	2.3
April 19, 1972	2046–2117	12.7	0.035 ± 0.009	4.0 ± 0.7	11.0	1.3

* The plasma temperatures for the first four cases are obtained to be 3.6 keV, whereas 3.0 keV for the last case.

Simultaneously with the balloon flight, Sco X-1 was observed photographically with a 12-inch reflecting astrograph at the balloon launching station at Hyderabad and with an 8-inch astrograph at Nizamiah Observatory, and photoelectrically with a 48-inch reflector at Rangapur Observatory. All these optical data were consistent with each other in overlapping periods. Absolute X-ray intensities in three energy ranges, 17.3 to 22.3 keV, 22.3 to 27.1 keV and 27.1 to 31.8 keV from Sco X-1 on April 16 are shown in Fig. 1, with B magnitudes. They vary in parallel to each other. The optical luminosity increased by about 0.2 mag (around 2245 UT), while the X-ray intensity also increased by a factor of 2. In Fig. 1 we also show the apparent temperature that is derived by fitting the

X-ray spectrum in the energy range 20 to 40 keV to the exponential spectrum. In the previous papers^{2,3} the apparent temperature was defined by fitting the observed X-ray spectrum to the thermal bremsstrahlung spectrum with the energy-dependent Gaunt factor. The apparent temperature found here is lower than that obtained with the method used before.

The hard X-ray spectra obtained in selected periods of the two flights are compared with those of the previous flight on May 1, 1971, in Fig. 2. The B magnitudes, X-ray intensities and apparent temperatures on the assumption of the exponential spectrum in these selected periods are listed in Table 1. A positive correlation between X-ray and optical emissions is clearly observed in the optically bright phase, whereas the apparent temperature shows only a weak positive correlation, in agreement with our previous result^{2,3}. On the other hand, rather strong positive correlations have been reported for lower X-ray energies⁴⁻⁶.

The observed features can be interpreted in terms of thermal bremsstrahlung from a hot, semi-opaque plasma. Thermal bremsstrahlung X rays are subject to Compton scattering by hot electrons. So the spectrum of X rays is considerably modified in the energy range 1 to 10 keV (refs 7–9), whereas only minor modification is predicted in the energy range above 20 keV, as is revealed by a theory of photon transport (unpublished work by J. N.). In the optical region free-free absorption suppresses the intensity of radiation emitted. Essential features of the spectrum are dictated chiefly by the optical depth for electron scattering τ_{es} , and also to some extent by the electron density and the shape of the plasma. For comparison with our experimental data, we have drawn theoretical X-ray spectra for several optical depths (S. H., M. M. and I. K., unpublished). The calculated spectra are in essential agreement with the observed ones in non-flaring and flaring periods, respectively, if the total mass of plasma particles is increased by about 40%. In all cases the plasma temperatures are found to lie in the range 3.5 to 3.8 keV.

Properties of Sco X-1 obtained by the simultaneous X-ray and optical observations are summarised as follows:

(1) The X-ray intensity in the energy range 20 to 40 keV shows a positive correlation with optical luminosity in the bright phase of Sco X-1. In general the amplitude of X-ray variability is much larger than that of optical luminosity.

(2) The apparent temperature of Sco X-1 derived from the spectrum in the energy range 20 to 40 keV does not appreciably change in comparison with considerable spectral variations in the energy range 1 to 10 keV. The plasma temperature does neither appreciably change during our observations.

(3) Flare activity is associated with an increase of the total mass of a hot plasma.

It should, however, be noted that on a few other occasions less steep spectra and higher intensities have been observed in optically less bright periods. Among these cases properties of Sco X-1 in the period of $m_B > 12.9$ may be different from those we are concerned with. An exceptional result was found by Miyamoto *et al.*¹⁰ who observed an intensity twice as high as ours in the flaring period and a less steep spectrum for $m_B = 12.6$. According to Uhuru observations, the correlation between X-ray and optical emissions in some rare periods

Fig. 1 Time variations of X-ray and optical emissions observed on April 16, 1972. B magnitudes indicated by open circles and black dots were obtained by the photographic observation with a 12-inch reflector and by the photoelectric observation with a 48-inch reflector. The apparent temperature kT is derived by fitting the observed spectrum to the simple exponential form. The X-ray intensities in three energy ranges are obtained by subtracting the background counting rates and correcting for the effective area of the counter and the atmospheric absorption. a, 17.3 to 22.3 keV; b, 22.3 to 27.1 keV; c, 27.1 to 31.8 keV.

Fig. 2 Hard X-ray spectra observed in five selected periods. For comparison theoretical spectra are given for three periods in the 1972 flights with the values of plasma parameters given in Table 1. May 1, 1971: ●, 2009 to 2018 UT, $B=12.6$; ○, 2057 to 2106 UT, $B=12.4$. April 16, 1972: open diamond, 2217 to 2225 UT, $B=12.5$; hatched diamond, 2241 to 2246 UT, $B=12.3$. April 19, 1972: cross-hatched diamond, 2046 to 2117 UT, $B=12.7$.

is different from that observed in most periods (H. Gursky, unpublished). Thus further comprehensive research will be demanded in order to construct a convincing model for any case of Sco X-1.

We thank the staff of the Balloon Facility of the Tata Institute of Fundamental Research for launch support and hospitality; Professors R. V. Karandikar of Nizamia Observatory and M. Huruhashi and K. Osawa of Tokyo Astronomical Observatory for arrangement for the optical observations. The work was partially supported by the Japan Society of Science Promotion.

Origin of neutron star magnetic fields

PULSARS are generally thought to be rapidly rotating neutron stars which have poloidal magnetic fields with intensities consistently in the range 10^{12} – 10^{13} gauss (ref. 1). Most of them are believed to evolve from main sequence stars with original masses of >1.4 – $8 M_{\odot}$. Evolutionary computations^{2,3} indicate that stars in this mass range develop a dense core of carbon and oxygen in which carbon begins to burn when the temperature reaches about 3×10^8 K and the density about 3×10^9 g cm⁻³. The rapid production of energy during this carbon-burning stage drives almost the entire core into convection for an extended time of the order of 10^{11} s (ref. 4), with convective velocities of the order of 10^4 cm s⁻¹ (ref. 5), provided that the rate of cooling through the convectively driven 'Urca process' is sufficiently high to stabilise carbon burning and to prevent the core from detonating and dispersing. If this sequence is a reasonable approximation to reality then the existence of neutron star pulsars suggests that carbon burning is, in fact, stabilised until electron capture, or some other process, causes part of the core to collapse to a neutron star²⁻⁷.

The origin of pulsar magnetic fields with nearly uniform intensities¹ is a matter of some interest. If a main sequence star with dimensions of $\sim 10^{11}$ cm contains a poloidal field, of about 100 gauss in its interior, then conserved magnetic flux during collapse to neutron star dimensions of $\sim 10^6$ cm will produce a magnetic field of the order of 10^{12} gauss. This line of argument is usually relied on in discussions of the origin of the magnetic fields of pulsars. We have argued (not yet published) that turbulent transport and mixing of the magnetic field, during the convective carbon-burning stage, will dominate its behaviour in the core. In this case the simplest notions of conserved magnetic flux do not apply, the accepted line of

reasoning fails and the final magnetic field of the collapsed neutron star is not a unique descendant of the field which the star possessed while on the main sequence.

Also in this connection, Ruderman and Sutherland⁸ have suggested that turbulent convection during the carbon-burning period will produce an equipartition magnetic field with an energy density equal to the kinetic energy density of the convecting fluid. The final state reached by a turbulent, conducting fluid and magnetic field has not, however, been resolved, so this suggestion must be considered speculative. Although we feel that such speculation is along the right lines, it contains a difficulty which, to us, seems significant. According to Ruderman and Sutherland⁸ an initial seed magnetic field, B_s , of spatial scale R , is rigorously frozen into the fluid and stretched and tangled by the turbulence until it attains an equilibrium intensity, B_{eq} , such that the energy density of the magnetic field is equal to the energy density of the turbulence. A convective core with radius $R \sim 10^8$ cm, and with an average density of 10^9 g cm⁻³, produces an equipartition magnetic field with $B_{eq} \sim 10^9$ gauss. It follows, however, that in the absence of some specially contrived fluid velocity which is a function of the magnetic field, the final field will have a spatial scale, δ , given by

$$\delta \sim R \sqrt{(B_s/B_{eq})}$$

Using the discussed values, $\delta \sim 3 \times 10^3 \sqrt{B_s}$ cm; even with a seed field as large as 10^5 gauss, $\delta \sim 10^6$ cm. Collapse through two orders of magnitude in radius, to the dimensions of a neutron star, then results in the neutron star magnetic field having a scale of $\sim 10^4$ cm and an intensity of $\sim 10^{13}$ gauss. Therefore, the surface magnetic field of a neutron star consists of some 10^4 patches of magnetic field with intensities of 10^{13} gauss, with randomly varied polarities. Each patch has a magnetic flux of $\sim 10^{21}$ gauss cm². The mean net flux through a hemisphere of the neutron star is then expected to be $\sim \sqrt{(10^4) \times 10^{21}}$, which is $\sim 10^{23}$ gauss cm². This is about an order of magnitude below what is inferred to be characteristic of pulsars¹. Furthermore, this process of magnetic field amplification leads to a large statistical spread in the net magnetic moments of neutron stars. The uniformity of neutron star magnetic moments, as inferred from the observed properties of pulsars, seems to indicate that the magnetic fields are produced with large spatial scales as well as with uniform intensities.

We suggest that convection during the carbon-burning stage (before collapse to a neutron star) in a massive, rapidly and differentially rotating, degenerate stellar core, leads to the production of a large scale magnetic field within the core itself, through the action of a hydromagnetic dynamo. Solutions of the hydromagnetic dynamo equations⁹⁻¹¹ use a dimensionless number, N , known as the dynamo number^{12,13}:

$$N = \gamma \Gamma R^3 / \eta^2$$

where γ is the rate of nonuniform rotation, Γ is essentially the cyclonic component of the convection in a rotating body, R is the spatial scale of the dynamo region and η is the magnetic diffusivity. We have calculated (not yet published) the conditions which will produce a quadrupole like magnetic field confined to the convecting core of a star. A magnetic field will be generated if the fluid motions are such that N falls within the range of $\sim -3,400$ to $\sim -12,000$. In a turbulently convecting core, transport and diffusion of the magnetic field will be dominated by turbulent mixing, and so we use the magnetic diffusivity, $\eta \sim 0.1 \nu_t \lambda$, where ν_t is the turbulent fluid velocity and λ is the scale of the large turbulent eddies^{14,15} (which we take to be about a pressure scale height). Setting ν_t equal to the average differential fluid velocity¹⁵ in the convecting and differentially rotating core, a magnetic field is produced when the convection extends over 5–10 pressure scale heights, as is the case in the carbon-burning core. The e-folding growth time of the magnetic field intensity is calculated to be of the order of days ($\sim 10^5$ s) in the carbon-burning core. This is short compared with the time over which carbon burning occurs⁴, so the field has sufficient time during this stage of stellar evolution to reach a saturation value, which will be determined by the dynamics of the fluid flow. We have estimated the saturation value of the

mean magnetic field throughout the rapidly rotating degenerate core by equating the Coriolis force on the convection, to the magnetic field stress. We find the mean of the poloidal and toroidal components to be $\leq 10^9$ – 10^{10} gauss. This estimate should only be taken as an approximation. It has been calculated by neglecting density variations throughout the dynamo region and by using only the crudest hydrodynamic considerations. The final state of the magnetic field will depend on quantities not yet calculated, such as the fraction of the core which actually collapses to a neutron star. With this quantitative caution in mind, however, we suggest that such a dynamo magnetic field—with a spatial scale which is that of the core itself, and a poloidal intensity of the order of 10^{12} – 10^{13} gauss after collapse to neutron star dimensions—is the progenitor of pulsar magnetic fields.

We consider elsewhere¹⁶, further dynamical consequences of this hypothesis.

Lewisian age for the Scardroy Mass

Rocks of Lewisian aspect have long been recognised east of the Moine Thrust in Sutherland, Ross and Inverness. They were correlated with the Lewisian west of the Moine thrust on petrological grounds¹ and were originally considered to be unconformably overlain by Moine rocks². Sutton and Watson^{3,4} at first questioned this correlation, but later accepted the view that rocks derived from the Lewisian basement are exposed at

Fig. 1 Sketch map showing Lewisian 'inliers' (black) originally recognised by the Geological Survey within the area of Moine rocks (white). The Scardroy area, south-east of Achnasheen, is enclosed by a circle of dots. Vertical lines, Lewisian and younger rocks west of the Moine thrust; dots, Old Red Sandstone.

Abbreviations as in Table 1; Gt, garnet. Grid references as in Table 1.

Scardroy and elsewhere in central Ross-shire (Fig. 1), and take the form of sheets tectonically intercalated in the Moine succession⁵.

In order to test this hypothesis, Rb-Sr whole rock analyses were carried out on a suite of typical gneisses from the Scardroy sheet (Table 1). $^{87}\text{Sr}/^{86}\text{Sr}$ ratios were obtained on a 12-inch mass spectrometer, and Rb/Sr ratios were accurately determined by X-ray fluorescence⁶. Rb and Sr contents were estimated semiquantitatively only. The decay constant of ^{87}Rb was taken as $1.39 \times 10^{-11} \text{yr}^{-1}$. K-Ar dates of separated minerals are presented in Table 2. K was determined by flame photometry and ^{40}Ar by isotope dilution using an AEI MS-10 mass spectrometer. The decay constants for ^{40}K are $\lambda_{\beta} = 4.72 \times 10^{-10} \text{yr}^{-1}$ and $\lambda_{\epsilon} = 0.584 \times 10^{-10} \text{yr}^{-1}$. Full analytical details have been given elsewhere^{6,7}.

The Rb-Sr whole rock data yield an isochron age of $2,810 \pm$

120 Myr, with an initial $^{87}\text{Sr}/^{86}\text{Sr}$ ratio of 0.7039 ± 0.0007 (Fig. 2). The scatter about the least-squares fitted line is not accounted for by analytical error alone and an increase of errors by a factor of two is needed to obtain a valid fit.

The data prove beyond any doubt that the rocks of the Scardroy sheet are, indeed, Lewisian. The actual age obtained is well within the age range for early Scourian rocks west of the Moine thrust, dated by Rb/Sr, U/Pb and Pb/Pb methods⁸⁻¹⁰. This age has been interpreted as the time of Scourian metamorphism. The rather low initial $^{87}\text{Sr}/^{86}\text{Sr}$ value is in general accord with much published (and unpublished) isotopic work^{8,10,11} suggesting that Scourian gneisses are not produced by remobilisation of substantially older (> about 200 Myr) sialic rocks with average continental Rb/Sr ratios.

The K-Ar dates for hornblendes and biotites (Table 2) are mostly within the typical range of mineral dates found in the

Fig. 2 Rb-Sr whole rock isochron plot for analysed samples. Errors are at 95% confidence level: a, 0.7039 ± 0.0004 ; b, $2,810 \pm 120$ Myr.

British Caledonides^{12,13}. Sample MT-2c yields a date of 535 Myr and may not have been completely degassed during the Caledonian metamorphism.

In the western Glenelg Lewisian inlier immediately to the east of the Moine thrust at Loch Duich, where Caledonian effects are not nearly as intense as at Scardroy, most hornblende and biotites still yield K-Ar dates of approximately 2,200–1,600 Myr, whereas slightly further east in the eastern Glenelg Lewisian inlier at Loch Duich biotites and hornblendes already yield typical Caledonian dates (Moorbath, unpublished work).

We thank Dr. H. Welke for help in collecting the specimens, and R. Goodwin for technical assistance. This work was supported by a Natural Environment Research Council research grant.

Solid tides recorded with 1 m interval mechanical strainmeter

A TENSIONED-QUARTZ strainmeter, 1 m in length has successfully recorded solid tidal strain variations in the Cooney Observatory. The designed is based on the 10-m quartz catenary strainmeter already in use at Cooney¹ Vitreosil quartz rods (2-mm diameter) linked with 4-mm diameter

Vitreosil hooks comprise the standard. This is tensioned by a brass beam-balance mounted to the hornfels by two $\frac{3}{8}$ inch expanding bolts. A single $\frac{3}{8}$ inch expanding bolt supports the other end of the quartz standard. Mounted within the fixed body of the beam balance is the coil housing of a Tesa GT10 inductive displacement transducer. The sensor armature is connected to the balance arm, (rotating on flexure strips), entering the transducer coil without contact (see ref. 2 for details).

A low impedance output (sensitivity $500 \text{ mV } \mu\text{m}^{-1}$) is provided from the Tesa electronic unit by a buffer amplifier. A Multiscript Model 3 chopper-bar recorder was used in these tests, sensitivity corresponding to 200 nm full scale deflection. The trace can be resolved visually to 2 nm (4% of maximum tidal amplitude). Zeroing is achieved with the visual readout and the electrical output facility provided in the Tesa unit.

The chopper-bar recorder was used for long period signals, sampling at 6 s intervals. Short period records of noise level were taken on an analogue pen recorder. (The use of a shorter interval of quartz results in a considerably higher resonant frequency than for the 10-m instrument³.)

Installation involves drilling three holes in the rock and setting the expanding bolts which support the covers and

Fig. 1 Section of actual record obtained with the 1-m tensioned-quartz instrument.

instrument ends. The instrument is then mounted and set approximately. Fine adjustment of the length finally is made by varying the balance mass to obtain a zero reading on the electronic unit. The task takes no more than an hour; no special skills are needed.

We selected a site to make best use of available conditions. The Lower Cooney tunnel, (other strainmeters reported are placed in an upper complex) is 316 m below the topographical surface. A 12-m long, narrow chamber, situated 300 m into and parallel with this drive has been sealed off at both ends, entry being through a sealed door at one end. In addition, a 10 cm thick expanded polystyrene box surrounds the entire meter. Temperature variations of 4 mK occur within the insulated cover with a noticeable regularity of 20 to 30 min cycles. (Measurements were made with a thermistor bridge, resolution of $100 \mu\text{K}$.)

Figure 1 shows part of the record obtained with the 1 m interval strainmeter, taken 6 d after completion of the installation. The drift over this interval is 2 parts in 10^9 per hour. A drift curve for the same meter, installed on the thermally controlled measuring base⁴, is given in Fig. 2, showing that the wall-mounted unit is stabilising in an expected manner.

The 10 Hz bandwidth noise level is no greater than 0.4 nm peak-to-peak, giving a signal to noise ratio of better than 40 dB when the amplitude of the tide is large.

The amplitude of the tide rises to about 50 nm. This is greater than expected at this site for a 1 m interval. Records from 10 m interval instruments in the Upper Cooney complex indicate that a maximum strain of 3 parts in 10^8 is normal. Comparison between this 1 m instrument and a 10 m quartz catenary are also situated in the same chamber, will enable us to investigate this departure in due course.

Fig. 2 Drift curve of 1-m instrument mounted in test base³ (relative to stabilised steel).

Also under development, in the same chamber, is a 1-m interval floor-mounted strainmeter that is coupled to the Earth by brass plates resting on a thin bed of sand. One plate carries a modified Tesa GT10 probe which has its armature supported by two thin phosphor-bronze diaphragms. Clamped onto the other plate, in a horizontal attitude, is a 1 m length of Vitreosil tube (outside diameter 16 mm). The tube is connected to the transducer by a quartz wobble-pin, completing the measurement loop. So far we have been unable to achieve satisfactory continuous records with this instrument because of excessive instability. But because of the advantages of plates on sand in terms of rapid mount stabilities⁴ and ease of installation, we will continue to investigate this design. Separate studies of mounts⁵ and experience with a 10-m quartz-tube instrument using bolted rock joints¹ suggests the method should perform satisfactorily.

Initial drift being a function of mounting rather than the standard, has an absolute value independent of gauge length. A 1-m instrument will, therefore, require a longer settling time than a 10-m unit.

Future research should be aimed at obtaining a closer thermal coupling between the instrument and rock and that it be located in deep undisturbed rock. Records obtained from a 1-m corehole meter (possibly using a rock core as a standard) may bear a closer relationship to the phenomena being studied than any records obtained to date.

We thank N. Taman for constructing the three strainmeters mentioned and for assistance.

Obsidian hydration profile measurements using a nuclear reaction technique

AMBIENT water diffuses into the exposed surfaces of obsidian, forming a hydration layer which increases in thickness with time to a maximum depth of 20-40 μm (ref. 1), this layer being the basic foundation of obsidian dating^{2,3}.

We have used the resonance at a ^{19}F energy of 16.45 MeV (0.83 MeV centre-of-mass energy) (ref. 4) in the nuclear reaction $^1\text{H}(^{19}\text{F}, \alpha\gamma)^{18}\text{O}$ to measure directly the hydration profiles of obsidian samples. This technique has already been used to measure the hydrogen concentration profiles in lunar samples and other solids to depths up to 0.4 μm with a resolution of 0.02 μm (refs 5 and 6). A second strong resonance at 17.64 MeV is encountered in extending these measurements to greater depths⁴, but its contribution can be unfolded from the data.

Fig. 1 Raw data for sample 5 (●) and for an unhydrated (0.3% H_2O) (▲) sample. Error bars indicate uncertainties arising from counting statistics. The background problem for $E_0 > 20$ MeV is illustrated by the profile for the unhydrated sample; a corresponding increase in counting rate occurs for all samples at $E_0 > 20$ MeV. To minimise this background, the interpolated data for the unhydrated sample were subtracted point-by-point from the data for sample 5. Then, for data points at energies $E_0 > E_R = 17.64$ MeV, the effects of the second resonance at E_{R2} were unfolded in accordance with equation (3) in the text: K_2 multiplied by the number of counts at $E_0 - \Delta E$ was subtracted from $Y_1(E_0)$ to obtain the unfolded hydration profile (b). The error bars in b indicate the propagation of errors contributed by uncertainties arising from counting statistics in the data for sample 5 and the unhydrated sample, and the unfolding of the second resonance. Using a calibration sample of known H content, the counting rate was converted to a weight % H_2O scale: using tabulated stopping powers⁷, the E_0 scale was converted to a depth scale. The segment of maximum H_2O gradient (for b, for example, at $1.2 \pm 0.2 \mu\text{m}$) was interpreted as corresponding to the thickness of the optically observed hydration band.

Table 1 Summary of the quantitative data derived from the measured hydration profiles (see Fig. 1)

* Thickness of hydration layer was not measured directly using the thin-section technique but was estimated from the known time of exposure of the fresh surface.

† Large uncertainty because of poor sample preparation.

The '% H₂O by weight' was assigned to the plateau value of the H₂O concentration profile for the sample, with uncertainties determined by finding the highest and lowest horizontal lines that could be construed to comprise the plateau. The thicknesses of the hydration bands given by the ¹H(¹⁹F, αγ)¹⁶O measured profile were obtained by taking the midpoint of the segment of maximum H₂O gradient on the sample profiles. The uncertainty is determined by the depths corresponding to the endpoints of the segment of maximum concentration gradient. The two values of H₂O content and hydration-layer thickness, as measured by the ¹H(¹⁹F, αγ)¹⁶O technique, for samples 7 and 9 may reflect the existence of two plateaux in their profiles. A possible systematic error introduced by our calculated stopping powers into the measurements of both hydration-band thickness and H₂O content has not been taken into consideration; the calculated stopping power has roughly a 5% uncertainty. Thicknesses of hydration bands, optically determined by microscopic examination of thin sections from the same obsidian samples, are given for comparison.

If a monoenergetic beam of ¹⁹F⁺ ions with energy E_0 slightly above the resonance energy E_R is focused on an obsidian sample, the ions gradually slow down because of electronic collisions (the rate of energy loss being characterised by the stopping power dE/dx of the obsidian) until at a depth X_R the resonance energy E_R is reached. At resonance, the nuclear reaction—in particular the γ-ray production—proceeds at a rate proportional to the hydrogen concentration in a thin layer at X_R . Assuming that all hydrogen present in the hydration layer is incorporated as H₂O, the reaction therefore proceeds at a rate proportional to the water concentration at X_R .

As the beam penetrates still deeper into the sample than X_R , the ¹⁹F energy decreases below the resonance energy. Because the nonresonant cross section on either side of the resonance energy is negligible compared with the cross section at resonance, the hydrogen outside the layer at X_R contributes negligibly to the total reaction yield. Since the stopping power dE/dx is very nearly constant in the relevant range of ¹⁹F energies (16 to 22 MeV) (ref. 7), the depth X_R is related to the incident beam energy E_0 by

$$X_R = (E_0 - E_R)/(-dE/dx) \quad (1)$$

(dE/dx is a negative quantity). Thus, measuring the γ-ray production rate as E_0 is varied gives a direct indication of water concentration as a function of depth in the target.

Since there actually are two resonances (at $E_{R1} = 16.45$ MeV and $E_{R2} = 17.64$ MeV), three situations are possible: $E_0 < E_{R1}$, $E_{R1} < E_0 < E_{R2}$ and $E_{R2} < E_0$.

If $E_0 < E_{R1}$, the ¹⁹F ions are gradually slowed down in the obsidian and the ion energy never reaches either resonance. Hence, the γ-ray production for $E_0 < E_{R1}$ is very small and defines the background level below the resonance.

If $E_{R1} < E_0 < E_{R2}$, the ¹⁹F ions will lose energy in the obsidian, and will eventually reach E_{R1} at a depth X_{R1} and

produce γ-rays at a rate proportional to the hydrogen concentration at X_{R1} . That is:

$$Y_1(E_0) = Y_{R1}(E_0) = K_1 W(X_{R1}) \quad (2)$$

for $X_{R1} < \Delta E/(-dE/dx)$, where K_1 is a measurable proportionality constant determined by the width and cross section of the resonance and the stopping power dE/dx , $Y_1(E_0)$ is the total γ-ray production rate, $Y_{R1}(E_0)$ is the rate of γ-ray production due to the resonance at energy E_{R1} as a function of E_0 , $W(X_{R1})$ is the water concentration at depth X_{R1} , and $\Delta E = E_{R2} - E_{R1} = 1.19$ MeV.

If $E_{R2} < E_0$, the ¹⁹F ions will, after losing some energy in penetrating the obsidian, reach both resonance energies, but at different depths X_{R1} and X_{R2} . So,

$$Y_1(E_0) = Y_{R1}(E_0) + Y_{R2}(E_0) \\ = K_1 W(X_{R1}) + K_2 W(X_{R2})$$

where K_2 is a second proportionality constant differing from K_1 because of different resonance parameters. But since $X_{R2} = X_{R1} - \Delta E/(-dE/dx)$,

$$Y_1(E_0) = K_1 W(X_{R1}) + K_2 W(X_{R1} - \Delta E/[-dE/dx]) \quad (3)$$

for $X_{R1} > \Delta E/(-dE/dx)$. So for a given E_0 , the contribution of γ-ray counts related to the resonance at E_{R2} is proportional to the H₂O content at a shallower depth than X_{R1} , the depth corresponding to the contribution due to E_{R1} . At this shallower depth, however, ($X_{R2} = X_{R1} - \Delta E/[-dE/dx]$), the H₂O concentration has already been measured by the first resonance at E_{R1} using a lower ¹⁹F beam energy ($E_0 - \Delta E$). Thus, the contribution $K_2 W(X_{R1} - \Delta E/[-dE/dx])$ from the second resonance can be calculated from other data (the constant K_2 having been independently determined) and may be subtracted from $Y_1(E_0)$, leaving only $K_1 W(X_{R1})$, the contribution from the first resonance. In this way $W(X_{R1})$, the water concentration as a function of depth in the obsidian target, may be determined by measuring $Y_1(E_0)$ and applying this simple un-

Table 2 Comparison of water content (in percentage by weight) of hydrated and unhydrated obsidian samples from the same source

Sample location	Intrinsic unhydrated % H ₂ O	Hydrated saturation level % H ₂ O
Bodie Hills, California	0.21 ± 0.04	2.31 ± 0.20
Coso, California	0.23 ± 0.07	2.68 ± 0.25
Borax Lake, California	0.35 ± 0.09	3.32 ± 0.32
East Dago Valley, California	0.66 ± 0.06	3.47 ± 0.25

The unhydrated surfaces were freshly chipped from the interiors of obsidian samples, and thus had no significant exposure to ambient water. The hydrated samples all had hydration profiles whose saturation plateaux extended deeper than the 2 μm limit of our depth range. There is a monotonic relationship between intrinsic and hydrated water concentration levels; the higher the intrinsic concentration of water, the higher the final saturation level. This suggests a possible relationship between the factor which determines the intrinsic water content and the mechanism by which ambient water diffuses into obsidian.

folding procedure. With the present experimental configuration^{5,6}, γ rays are detected with an efficiency of 0.022, using a 7.6 cm \times 7.6 cm NaI (TI) scintillation detector.

We made hydration profile measurements as follows on a number of obsidian samples with hydration bands less than 2 μm thick. Raw data (γ -ray counts per 3 μC of $^{19}\text{F}^{4+}$ against E_0) were taken over an energy range of 16 to 22 MeV. The beam current was sufficiently low that the hydrogen concentration was not perturbed, that is, subsequent measurements on the same samples gave virtually identical results. The counting rate (Y) was converted to water concentration by comparison with a standard chlorite sample of known H content, and other mineral standards.

A value of 2.4 g cm⁻³ for the density of hydrated obsidian, and values of stopping powers taken from Northcliffe⁷, were used to compute dE/dx for ^{19}F ions in the obsidian (~ -2.3 MeV μm^{-1}). Using this value of dE/dx in equation (1), the ^{19}F energy scale was converted into a depth scale. (The depth resolution is determined by the ratio of the resonance half width to the stopping power and is about 0.02 μm at the surface; energy straggling gradually reduces the resolution to about 0.04 μm at a depth of 2 μm . Because of background problems at higher energies, this technique is limited to depths of $\lesssim 2$ μm .)

The hydration layers of samples 1–4 (Table 1) were sufficiently narrow that the second resonance was not encountered and unfolding was unnecessary, so the raw data were plotted directly. But since the contribution of the natural linewidth of the resonance to the observed energy width of the hydration layer is significant for such thin layers, correction for this effect was made in order to obtain the measured values for the thickness of the hydration layer.

For samples 5–10, data from an unhydrated obsidian sample (water content uniformly 0.3%) were subtracted point-by-point from the raw data to minimise background problems for $E_0 > 20$ MeV. (For this reason, the zero point of the water concentration scale is displaced by 0.3%.) The profile was then unfolded (equation 3) to leave only the contribution from the resonance at 16.45 MeV. These reduced data were then plotted and were fitted with the calculated water content and depth scales. This procedure is illustrated for sample 5 in Fig. 1.

The detailed hydration profiles can be used to obtain information about the mechanism of water diffusion into obsidian and the factors which influence hydration. First, the general shape of the diffusion profiles agrees qualitatively with that espoused by Friedman and others^{1–3}, characterised by a saturated hydration plateau followed by a steep diffusion front, rather than the more conventional exponential profile suggested by Marshall⁸. Occasionally, however, the data suggest either a double plateau level or that the top of the hydration plateau has an appreciable slope, as in samples 7 and 9, which may indicate the existence of more than one

mechanism of water diffusion and binding as proposed by Ericson, MacKenzie, and Berger⁹.

Table 1 shows that the thickness of the hydration layer corresponding to the maximum gradient of water concentration obtained from our measurements agrees reasonably well with the layer thicknesses obtained from the optically measured thin sections. This seems plausible on theoretical grounds since the hydration band is visible under cross-polarised light because of stress birefringence, with the border between hydrated and unhydrated regions corresponding to the line of maximum stress⁹. (Under ordinary light, the demarcation between hydrated and unhydrated glass is given by a dark line which is the line of maximum gradient of the water concentration⁹.) Indeed, a set of tektite samples with measured H₂O distributions characterised by gently sloping exponential diffusion profiles rather than the steep diffusion fronts observed in hydrated obsidians, did not have visible hydration bands in thin section. (The tektites we measured all had exposure times of roughly 700,000 yr, according to K–Ar and fission track dates, and were recovered from laterite soils in South-east Asia. Two samples, of the splash-form type, were recovered in the early 1960s; a third sample, recovered in the later 1960s, is from the Muong Nong site (J. O'Keefe, private communication).)

Our resolution of 0.02 μm represents a significant improvement over the resolution of 0.1 or 0.2 μm achieved with optical techniques². The uncertainty in our measurements of the thickness of the hydration layer is limited by the finite slope of the concentration decrease for the layers 1–2 μm thick; it is not a limitation imposed by our technique (except where the spacing of data points has been wider than optimum), but by the actual profile itself.

Second, as a result of our measurements of H₂O concentrations in hydrated and unhydrated samples from the same source, it would seem that the higher the intrinsic (unhydrated) concentration of water in a given obsidian sample, the higher the final saturation level (Table 2). (Tektites have extremely low intrinsic water content compared with obsidians¹⁰; this possibly indicates differences in their internal structure, as proposed by Berger and Ericson¹⁰, which might explain the qualitatively different hydration profiles.) This correlation supports previous findings by Kimberlin¹¹.

Third, it seems that, for a set of samples from the same obsidian source exposed for equal times¹², the saturation concentration of water is weakly correlated with the thickness of the hydration layer (Table 1, samples 6–9).

Fourth, we observed a progressive increase in hydration depth with hydration time for the artificially hydrated samples (Table 1, samples 1–3). This type of experiment should prove particularly useful in investigating variations of hydration rate with chemical composition, since the hydration can be carried out under controlled conditions.

Using a similar technique with the resonance $^{23}\text{Na}(p, \gamma)^{24}\text{Mg}$ at 1.318 MeV (ref. 13), we have measured the sodium depth distributions to a depth of 1 μm in obsidian samples 1 and 4 to check a hypothesised ionic-exchange diffusion mechanism which predicts a sodium depletion in the hydration layer⁹. We found no significant variation of sodium content between the layer and the intrinsic unhydrated obsidian; however, we were limited by counting statistics to a detection threshold of about 10% variation in the Na content.

Resonant nuclear reaction techniques of this type may be extended to many other diffusion problems. What is required is a strong, isolated resonance which can be associated unambiguously with the diffusing agent under investigation. The technique provides a relatively nondestructive method of measuring diffusion profiles directly on a microscopic scale.

We thank Dr D. S. Burnett for suggesting the application of this nuclear reaction technique to obsidian hydration measurements, and R. H. Goldberg and W. Long for technical assistance. We also thank Dr J. O'Keefe, NASA, for the tektite samples and Dr C. W. Meighan for the hydration

measurements through the Obsidian Hydration Laboratory, Department of Anthropology, University of California, Los Angeles. This work was supported in part by the National Science Foundation.

Using artificial thermoluminescence to reassemble statues from fragments

THE thermoluminescence (TL) of marbles and limestones¹⁻³ from various quarries in Greece⁴ has been described. It had been hoped that features characteristic of each quarry would be found. The glow curves of samples as taken from the quarry are called natural thermoluminescence curves (NTL). These curves did not allow any determination of origin, because in nearly every case only a single peak was obtained.

Glow curves of artificial thermoluminescence (ATL) provide considerably more information. ATL glow curves were obtained by heating samples until the NTL was erased, then exposing them to X rays at room temperature, and subsequently heating them at a constant rate.

Another type of glow curve, the curve of mixed thermoluminescence (MTL), was obtained by exposing untreated samples to X rays at room temperature and subsequently heating them up at a constant rate. With this kind of glow curve the ATL curve is superimposed on the NTL curve. Most MTL glow curves displayed three peaks, and thus supplied five parameters for the identification of each sample:

(temperatures T_1 , T_2 , T_3 ; and intensity ratios I_1/I_2 and I_2/I_3). A table of all five parameters in material from 36 quarries has been compiled. In some of the quarries, significant differences could be detected between samples from widely separated blocks. The differences were more pronounced between blocks of different colours.

Because of the differences in the parameters of samples from any one quarry, it is not possible to identify unambiguously the origin of any piece of marble. The differences between samples from any one block are, however, small, suggesting that there could be a good possibility of determining whether separate fragments of marble are from the same statue or slab. Only small quantities of powder are available for investigations of archaeological fragments. A comparison of powders (~ 0.1 g) from adjacent holes showed that the MTL glow curves give identical peak temperatures, although the intensity ratios were sometimes different. This could be because of differences in the degree of heating of the material during the drilling process, which depends on the pressure exerted.

The results are consistent if the comparison is made from the ATL glow curves (Fig. 1a and b) which are not affected by any heating during drilling. Although these usually have only three independent parameters: T_1 , T_2 and I_1/I_2 they differ very little (about 5° C for the temperature and 5% for the ratios on powders from adjacent drilling holes).

From a consideration of several glow curves of the same sample mean values of the parameters can be obtained, together with their standard deviations (Table 1).

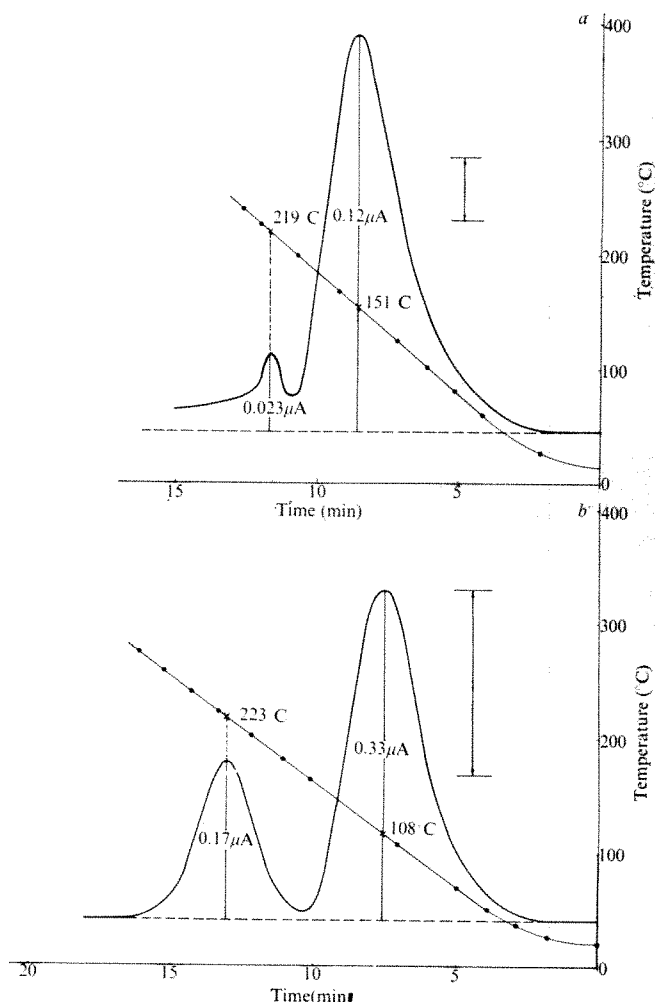

Fig. 1 ATL glow curves from two different blocks. The results were obtained on a chart recorder. Scale bars: a, 0.02 μ A; b, 0.2 μ A. The dependence upon temperature is shown on both graphs.

Table 1 ATL curve parameters

	T_1 °C	T_2 °C	I_1/I_2
Fig. 1a	108 ± 5	223 ± 4	1.9 ± 0.1
Fig. 1b	151 ± 5	219 ± 7	5.1 ± 0.6

If the parameters are the same, it does not necessarily follow that the fragments belong to the same block, as they could simply have originated in the same quarry. If, however, two fragments have different parameters it can be said with a high degree of certainty that they do not belong to the same block.

This method was of great assistance in the restoration of statues from fragments found in a shipwreck near the island of Antikythera.

An extensive description of the method will appear, in English, in the *Praktika* of the Athens Academy.

Mutant of bacteriophage T4D affecting expression of many early genes

IN T4 infections the mechanisms determining the time and rates of expression of early genes are not yet clearly understood. Although mutants which do not make late gene products or which are defective in DNA synthesis generally fail to turn off the synthesis of most early gene products, no mutations have been described which affect either the time of appearance or the initial rate of synthesis of proteins from more than a single early gene. This preliminary report describes the isolation and some of the properties of such a mutation. This mutation which maps between genes 52 and *t* defines a new regulatory gene.

When a lambda lysogen is singly infected at 37° C with a phage carrying temperature-sensitive mutations in both *rIIA* and in gene 42 (dCMP-hydroxymethylase¹), the infected cells quickly lose their ability to form a plaque at 30° C. After 25 min at the restrictive temperature only about 2% of the infected cells can still form a plaque at 30° C. It seemed possible that the survival of the *rIIA*-gene 42- infected cells might be increased by an additional mutation whose effect would be to prevent the expression of many early genes. That is, if the normal development of the phage-infected cell was suspended at an early stage then the early absence of functional *rIIA* product might not be lethal². On shifting such infected cells to the

permissive temperature, normal development might then proceed as active *rIIA* protein was synthesised. According to this rationale, the survivors of the heat treatment (25 min at 37° C) would include phage which were genetically less sensitive to this treatment. Among mutants thus selected there might therefore also be mutants controlling the expression of early T4 genes.

The selection was done by singly infecting *E. coli* K112-12 (λ h) #3/S at 37° C with the non-mutagenised double temperature-sensitive mutant *tsDG12* (*rIIA*³)-*tsL13* (gene 42). After 25 min at 37° C the infected cells were filtered and resuspended in fresh media at 30° C. The infected cells were lysed at 50 min by the addition of chloroform. This enrichment procedure was repeated several times using the progeny phage from one cycle of infection as the input phage for the next cycle. The infected cells in the fifth cycle of enrichment were significantly more resistant to the temperature treatment than cells infected with the parental phage. Stocks were made from isolated plaques of several of these surviving phage and one such isolate was thoroughly examined. Although this phage still contained both of the parental markers, about 20% of the K112-12 (λ h) #3/S cells infected with it (by comparison with only about 2% for the parental phage) could still make plaques on *E. coli* B (su⁻) at 30° C after 25 min of infection at 37° C. This phage contained a new mutation in addition to the two parental markers. This mutation, *tsG1*, when separated from the two parental markers is itself a temperature-sensitive mutation. It seems to reduce the lethal effects caused by the initial absence of functional *rIIA* protein, but not the lethal effects due to the absence of functional gene 42 product (P42) (manuscript in preparation).

Figure 1 presents the results of two-factor crosses which show that *tsG1* maps in the region between *amH17* (gene 52) and *amtA3* (gene *t*). The mapping of *tsG1* to the right of *amH17* is consistent with the results of a three-factor cross between *tsG1* and the double mutant *amH17-ac*³. Most of the *ts*⁺-*am*⁺ recombinants (78 out of 103) examined were sensitive to acridine.

Reversion studies suggest that *tsG1* is a point mutation. In three isolated plaques of *tsG1* grown at 30° C revertants appeared at an average frequency of 1×10^{-6} . Experiments with one of these *tsG1* revertants showed that it was like wild type at both 30° C and 42° C in its growth in liquid medium and in its pattern of protein synthesis as seen on SDS-polyacrylamide gels (data not shown). This revertant was crossed to wild type and 870 progeny phage tested for their temperature sensitivity. No *tsG1* segregants were found. On this basis it is concluded that *tsG1* is a point mutation and that reversion can occur at the site of the original lesion or very close to it.

The mutants *tsG1* and *amH17* (gene 52) complement one another in a mixed infection of *E. coli* B^E at 42° C in the sense that the mixed infection begins to produce progeny at the same time

Fig. 1 Mapping by two-factor crosses. Log phase *E. coli* B^E grown at 37° C to 10^8 ml⁻¹ in M9S medium¹⁰ containing 0.2% casamino acids (Difco) were centrifuged and resuspended at 2×10^8 ml⁻¹ in fresh medium. Crosses were done at 30° C using a multiplicity of infection of five for each parent. After 3 min of adsorption the infected cells were diluted 10^4 into fresh medium and aerated by bubbling. Chloroform was added at 50 min to ensure complete lysis. Progeny were assayed on plates made of EHA bottom and top agar¹¹. Total progeny were assayed at 30° C using *E. coli* B₄₀ sul⁻ as indicator. Wild type recombinants from all crosses were selectively assayed on plates seeded with *E. coli* B^E and incubated at 42° C. The map distances given are 200 times the frequency of wild type recombinants scored in crosses between the markers indicated. *tsG1* and *amH17* each recombine with the terminal *rIIB* marker, *r73*, to about the same extent, giving a map distance of approximately 15 units.

as a wild type infection and not with the delay characteristic of either *amH17* or *tsG1* (data not shown). The pattern of protein synthesis seen in *amH17* infections (see below) is also quite different from that observed in *tsG1* infections. It is therefore very unlikely that *tsG1* is in gene 52.

In addition *tsG1* is not in the *t* gene for the following reasons. The *t* mutants specifically affect late events in T4 development (lysis and the shutoff of macromolecular synthesis³) but the early events seem to be entirely normal (ref. 3 and H. Krisch, personal communication). In mixed infections at 42° C *tsG1* complements the late lysis phenotype of *amtA3* mutation and progeny phage are produced at the same time as in wild type infections (data not shown). As there are no other known genes in the gene 52 to *t* region, the *tsG1* mutation defines a new gene which is called *mot* for modifier of transcription.

SDS-polyacrylamide gel analysis of the proteins synthesised after infection of *Escherichia coli* B^F (*su*⁻) at 42° C with *amH17* or with *tsG1* is presented in Fig. 2. *amH17* was used as the control in this experiment because it maps close to *tsG1* and because it⁴ as well as *tsG1* has a DNA synthesis delayed phenotype. The initial rates of synthesis of the proteins as seen on these gels are identical in *amH17* and in wild-type infections (unpublished observations). Many differences between the *amH17* and *tsG1* infections can be seen. Since nearly the same amount of radioactivity precipitable by trichloroacetic acid was layered on each gel, differences in band intensities for individual proteins reflect differences in their relative rates of synthesis. In *amH17* infections the band corresponding to the *rIIA* protein is quite dense in the 2–6 min labelling, decreases in intensity during the 6–10 min labelling and is even less dense in the 10–14 min pulse. But in *tsG1* infections the *rIIA* band is at least as dense in the 6–10 min labelling as in the 2–6 min labelling and a considerable amount of it is still being synthesised in the 10–14 min pulse although its rate of synthesis is then slightly less than in the 6–10 min pulse. Other experiments show that in *tsG1* infections detectable amounts of *rIIA* protein are still synthesised as late as 35–40 min after infection at 42° C. Thus in *tsG1* infections the *rIIA* protein is synthesised for a considerably longer time than in either *amH17* or wild-type infections.

There are many mutants of T4 which affect the normal turnoff of early gene functions: maturation-defective genes (33 and 55)^{5,6}; the DNA-delayed mutants⁷ and all of the DNA-negative mutants^{1,7}, have this property to varying extents although synthesis of the *rIIA* protein is not affected by any of these mutants to the extent that it is affected by *tsG1*. But *tsG1* is different in a much more important respect from all other mutants having an effect on early gene turnoff. After infection with all these mutants the initial rates of synthesis are normal for all the early proteins which have been studied. Though most of the phage induced proteins do appear at the normal time in *tsG1* infected cells, the initial rates of synthesis for some of them are considerably reduced (see Fig. 2). The products of genes 43, 45 and *rIIB* are detectable during the first labelling period but their rates of synthesis are significantly reduced. P43 and P45 seem to be more severely affected than *rIIB*. Whereas most of the proteins from *tsG1* infections as seen on these gels appear at the normal time a few are not detectable during the first or even the second labelling period. For example, the band migrating at the position of the gene 32 protein is not visible until the 6–10 min labelling period.

The effect of *tsG1* on the expression of the *rIIB* protein is of special interest because it suggests an hypothesis for the mode of action of the *mot* gene product. Schmidt *et al.*⁸ have shown that the *rIIB* cistron is transcribed as part of a polycistronic message which includes the *rIIA* species and that it is also transcribed from a promoter located between the *rIIA* and *rIIB* cistrons. Preliminary evidence indicates that early after infection there is less *rIIB* transcription relative to *rIIA* transcription in *tsG1* infected cells than in cells infected with wild type. Since at early times in *tsG1*-infected cells there is a relative lack of *rIIB* message and protein but a normal amount of *rIIA* protein we hypothesise that in *tsG1* infected cells transcription from the

Fig. 2 SDS-polyacrylamide gel analysis. *E. coli* B^F (*su*⁻) grown in M9S containing 0.2% casamino acids to 10^8 ml⁻¹ was centrifuged and resuspended at 5×10^8 ml⁻¹ in M9S* (M9S containing only 10% of the normal amount of casamino acids). One millilitre of cells warmed for 2 min at 42° C were added to 24 ml of M9S* at 42° C containing either *tsG1* or *amH17* at 2×10^8 ml⁻¹. At 1, 2, 6, and 10 min after infection 5 ml aliquots of the infected cells were transferred to tubes at 42° C containing 5 μ Ci of a mixture of 15 ¹⁴C-labelled amino acids (NEN 445). The pulses 1–3, 2–6, 6–10 and 10–14 min were terminated by the addition of a 20-fold excess of unlabelled casamino acids. After a 3 min chase the samples were chilled by addition of ice and then centrifuged. The pellets were resuspended in 0.25 ml of 0.01 M Tris pH 7.5 and 1.0 ml of sample buffer (10% glycerol, 5% 2-mercaptoethanol, and 3% sodium dodecyl sulphate in 0.0625 M Tris pH 6.8) and then placed in boiling water for 3 min. Disc 10% SDS-polyacrylamide gels were prepared as described by Laemmli¹². The gels were run at a constant current of 1–2 mA per tube and were stained, sliced, dried and exposed to X-ray film as described by Fairbanks *et al.*¹³. About 30,000 trichloroacetic acid precipitable counts were layered on each gel. The numbers on the left margin of the figure identify the genes coding for the proteins indicated. The band migrating just slightly faster than P32 is P44 (ref. 14). The absence of the gene 52 band in the early labellings with *amH17* is expected because *amH17* is in gene 52. The band appearing at the position of P52 in the last two labelling periods is a cleavage product of the main structural protein of the phage head. In the gels from the 1–3 min labelling, the migration of the proteins was not identical. The gels were matched in the P32–*rIIB* region and as a consequence the positions of P43 and *rIIA* in the gel from the *tsG1* infection are slightly lower than the corresponding bands in the gel from the *amH17* infection.

promoter located between the *rIIA* and *rIIB* cistrons is defective. Thus the normal *mot* gene product may have a positive role in transcription related to the recognition of promoters like the one between the *rIIA* and *rIIB* cistrons. The *mot* gene itself might code for this regulatory element or it may merely control

its expression. In either case the postulated positive transcriptional element could function similarly to the sigma-like factor described by Travers⁹.

Immunotherapeutic suppression in transplantable solid tumours

α -FOETOPROTEIN (AFP) is a glycoprotein, of unknown function, synthesised by the foetal liver and yolk sac of mammals¹. Increased serum levels of AFP in adults are indicative of either pregnancy or a pathological state, that is primary hepatocellular carcinoma, regenerating liver and teratoblastomas of the ovary and testis^{2,3}. Recently, abnormal levels of AFP in amniotic fluids have been correlated with foetal distress⁴. While attempting to study the physiological role of AFP during ontogenic and oncogenic growth, we have observed an interaction between AFP and its homologous antiserum that may have immunotherapeutic value. We report here the suppression of mouse hepatoma growth *in vivo* and *in vitro* using passively administered antiserum to AFP.

Amniotic fluid (AF) containing AFP was obtained from C57BL mice as described by Sell⁵. AFP was isolated from the AF by upward flow gel filtration on Sephadex G-75, followed by preparative polyacrylamide gel (PAAG) column electrophoresis using a modification of Gussev's method⁶. A single band could be demonstrated subsequently by disc PAAG electrophoresis. The AFP isolate was emulsified with equal amounts of Freund's complete adjuvant for use as an immunogen. New Zealand white rabbits were immunised twice weekly for 2.5 weeks by subcutaneous flank injections. The rabbit antiserum, collected 2 weeks after the last injection was

immunoreactive against mouse AFP, but not albumin, as determined by microimmunodiffusion. A single band in the α_1 position was demonstrated after immunoelectrophoresis. The antiserum was absorbed further with nonimmune mouse serum (NMS) to insure monospecificity. Using the absorbed anti-AFP serum, AFP was quantitated in mouse sera using radial immunodiffusion (unpublished results of G. J. Mancini and S. R. Young).

Male and female mice of the C57L/J inbred strain bearing the AFP-secreting hepatoma BW7756 (Jackson Laboratory) were used as the animal tumour model. A standard tumour growth curve was obtained during 30 d (after transplantation) using mice weighing 20–28 g. The transplanted tumours usually exhibited 100% takes. The anti-AFP antisera were tested against the hepatoma during this period by three *in vivo* and two *in vitro* methods. The *in vivo* testing included (1) administration of graded doses during tumour growth; (2) a large, single dose administered 2 d after implantation; and (3) incubation of the tumour inocula in test serum before implantation. The *in vitro* methods encompassed (4) the cytotoxic antibody assay, and (5) tissue culture cytopathic testing. The tissue culture experiments, however, will be described in detail elsewhere⁷.

The graded doses included alternate daily intraperitoneal injections (a total of 2.60 ml) of absorbed anti-AFP serum given in small divided doses during 28 d. Using method (2), a single large dose of absorbed antiserum (2.0 ml) was injected intraperitoneally into the mice 2 d after transplantation. Method (3) was performed by incubating the tumour inocula (1.0 mm² ml⁻¹ whole antiserum) for 30 min at 25° C immediately before implantation. The incubated tumour inocula were subsequently washed twice in Hanks balanced salt solution before implantation. All animals were observed and inspected daily for tumour growth over the post-transplantation period. At autopsy, 28 d later, all animals were bled and tumour weight and size were determined. For each experiment described above, nonimmune rabbit serum (NRS) absorbed with NMS was administered as control serum to an age-matched and weight-matched group of mice. The cytotoxic antibody assay was performed *in vitro* according to the method of Gorer and O'Gorman⁸. Fresh guinea pig serum was titred and used as a complement source. In some studies, only deactivated anti-AFP and NRS were used. For each determination, 3×10^6 – 4×10^6 screen-tested tumour cells were counted in a haemocytometer by trypan blue exclusion.

The *in vivo* methods of tumour growth suppression are compared in Table 1, which shows that antiserum administered gradually throughout incubation resulted in a 52% reduction in tumour size as compared with untreated controls (5% significance level). However, the NRS control group displayed a 20% reduction; thereby subtracting out to a final 32% reduction in the experimental group. Similarly, the animals

Table 1 The *in vivo* methods of immunotherapeutic tumour growth suppression are compared in C57L/J mice administered anti-AFP serum

Treatment groups	Mean	s.e.m.	Growth (%) reduction*	Significance level†
Graded dose (11) A·AFP	2.84	0.74	32.0	< 0.05
NRS	4.70	0.47		
Single dose (9) A·AFP	3.52	0.52	33.0	< 0.10
NRS	5.44	1.05		
Pre-incubated A·AFP	0.52	0.18	67.0	< 0.01
inocula (11) NRS	4.42	0.64		
Untreated (13) Control	5.87	0.50	0.0	—

tumour weight — tumour weight
× 100.

Untreated control
tumour weight

† Student's *t* test was used.

subjected to a single, large dose also underwent a 33% reduction in tumour growth even though the statistical significance of this latter experiment differed considerably from treatment with graded doses (10% compared with 5% probability level). Finally, treatment with incubated inocula demonstrated not only a high statistical significance (1% level) but also a 67% reduction in tumour weight. Thus, direct contact of the tumour cells in the test reagents before implantation resulted in cytotoxicity which was twice as effective as the other modes of treatment.

The results of the cytotoxic antibody assay *in vitro* are presented in Fig. 1. An innate cytotoxicity of nonimmune rabbit and guinea pig serum against mouse cells was observed which could be eliminated by a 1:10 to 1:16 serum dilution. Nonimmune rabbit serum control levels maintained a 70% tumour cell viability throughout a serum dilution range of 1:32 to 1:128. In contrast, the anti-AFP serum had a 100% cell killing effect at 1:16 and a 66% effect at 1:32 dilution. Unlike the NRS, which remained stable, the cytotoxicity of the AFP antisera could be eliminated uniformly by extension to a 1:128 dilution as evidenced by the cytotoxic index in Fig. 1. Thus, the complete cell cytotoxicity (CI = 1.0) could be titred out over three two-fold dilutions. If the innate cell cytotoxicity of NRS for mouse cells is subtracted out (as above), it could still be observed that anti-AFP exerted a 30–33% killing effect on hepatoma tumour cells *in vitro* above that of NRS. Further cytotoxic testing using anti-AFP serum indicated that complement (host or foreign) was not an absolute requirement for cell killing but its presence intensified the killing effect. Finally, the cytotoxicity of the anti-AFP serum could be abrogated by absorption with purified AFP.

The gross pathology observed during the 30 d included fibroid accumulation, serous exudation, loss of connective tissue capsule and massive haemorrhaging at the tumour site. By 28 d, much of the tumour mass presented as nonviable tissue in mice treated with anti-AFP serum. In contrast, the mice administered NRS displayed only occasional haemorrhaging about the tumour mass. The corresponding histopathology revealed the presence of mononuclear infiltrates which invaded the tumour tissue of the animals treated with AFP antiserum. The cellular infiltrate populations increased uniformly from the 14th to the 21st day, and by day 28 much of the tumour mass had been replaced by inflammatory tissue. However, the animals treated with NRS displayed only focal infiltrates with occasional ischaemic necrosis. The histopathological results, which were confirmed by Dr J. J. McCoy jun. of the Veteran's Administration Hospital, Columbia, South Carolina, will be reported in more detail in a forthcoming publication.

The presence of AFP in serum, determined quantitatively by radial immunodiffusion, was suppressed in the antibody-treated mice, while those subjected to NRS exhibited a steady increase in AFP serum concentrations. The mice treated with NRS displayed a nine-fold increase in serum AFP from the 14th to the 28th day after transplantation (final AFP concentration = 9.75 mg ml⁻¹). In contrast, the mice treated with anti-AFP serum showed a slight increase in AFP production from the 14th to the 21st day with a drastic decrease thereafter to the 28th (final AFP concentration = 0.38 mg ml⁻¹). Thus, the presence of AFP in the serum seems to correlate well with tumour status.

Our results indicate that humoral immunotherapy was effective against a progressively growing solid tumour. The passive administration of heterologous antiserum to AFP in tumour-bearing mice resulted in a suppression of hepatoma growth and a decrease in AFP production over 30 d. The greatest reduction in tumour size (67%) occurred when the tumour inocula were incubated directly in the test serum. When the antiserum was administered by two methods of intraperitoneal injection, tumour size was reduced 32%. Extrinsic complement was not used or added to the serum; however, the serum was not heat deactivated and complement

Fig. 1 Cytotoxic index for anti-AFP serum (exp) versus nonimmune rabbit serum (control) tested against mouse hepatoma target cells. Cytotoxic index is obtained from:

$$\frac{\text{Proportion of dead cells in control} - \text{Proportion of dead cells in exp}}{\text{Proportion of dead cells in control}}$$

may have been present in either the rabbit or mouse serum. In comparison with the *in vivo* test, the use of guinea pig complement *in vitro* also displayed a 30–33% cell cytotoxicity with direct incubation of teased tumour cells with various antibody dilutions. Neither native nor heterologous complement was required for *in vitro* cytotoxicity. Finally, the specificity of the cytotoxic reaction was demonstrated by absorption studies using purified antigen.

These experiments signify that some humoral factor or group of factors (anti-AFP) present in the sera of rabbits immunised to AFP induced growth retardation in progressively growing mouse hepatomas. One cannot rule out the possibility that soluble antigen–antibody complexes, present in the serum after absorption, were not involved in the observed suppression. Thus, the host defences may be responding to the presence of immune complexes in and about the tumour. In any case, the killing effect of the antiserum *in vivo* was probably due to (1) tumour cell-surface destruction, and (or) (2) vascular damage within and around the tumour mass. In either case, immune complexes would be formed which can act with or without complement. Since this immunotherapeutic approach is effective in tissue culture, the absolute requirement of active factors from the host mouse can be ruled out. The gross and histopathological evidence suggests that an Arthus-type tissue destruction occurred at the tumour site which, in effect, starved the tumour and retarded overall growth.

Since the function of AFP has not been established, it is unclear whether the actual blocking of AFP function played a role in the retardation of hepatoma growth. Some investigators have suggested that AFP functions in a growth factor capacity being essential for foetal liver and (or) hepatoma growth^{9,11}. Recently, indirect evidence has implicated AFP as a steroid (oestrogen) binding protein¹⁰. It is tempting to speculate that the tumour growth suppression reported here may have occurred at the level of hormonal induction of protein synthesis.

Inhibition of cell-dependent cytotoxicity as an assay for mouse alloantibody

MANY assays for alloantibody depend on functional activities of the Fc portion of the immunoglobulin molecule. These functional activities are acquired when the antibody binds to its target cell. Complement binding, as demonstrated by lysis or complement fixation, has been the most widely used of these activities. In man, alloantibody can also be detected by its ability to mediate cell-dependent lysis of target cells¹⁻³. In this system, effector cells (human peripheral blood leukocytes) lyse allogeneic chromium ⁵¹Cr-labelled target cells (lymphocytes) in the presence of the appropriate alloantibody, providing a sensitive, complement-independent assay for alloantibody. In contrast, we have found that mouse alloantisera do not usually mediate lysis of mouse target cells (lymph node lymphocytes, phytohaemagglutinin (PHA) blast cells, and tumour cells) by mouse effector cells (spleen cells). Data supporting this conclusion will be presented elsewhere.

In man, alloantibody has a second activity in this cell-dependent assay: namely, that when the antibody is directed against the effector cell it inhibits cell-dependent killing of antibody-coated target cells². We have found that mouse alloantisera have a similar effector-cell inhibiting capacity. Mouse spleen cells are excellent effectors for lysing antibody-coated xenogeneic target cells (in contrast to their inability to lyse alloantibody-coated allogeneic cells). When alloantibody directed against H-2 specificities of the effector cell is added, the lysis is abolished. This assay, which we refer to as the cytotoxicity inhibition assay (CIA) is the subject of this report.

The cytotoxic system used is similar to that of Perlmann⁴, using mouse spleen cells (effector cells) to lyse chicken red cells (CRBC) (target cells) in the presence of rabbit anti-chicken red cell antibody (RACA). Single-cell suspensions of mouse spleen cells in Eagles' minimal essential medium (MEM) with 5% foetal calf serum were placed in plastic culture tubes. The alloantiserum to be tested was added to these, with 10⁴ radio-active ⁵¹Cr-labelled CRBC and RACA (1/25,000) in a final volume of 250 μ l. All experiments are performed in triplicate. Sheep red cells were added at 10⁷ ml⁻¹ to lower background ⁵¹Cr release⁵. The mixture was then incubated at 37°C for 3 h in a 10% oxygen, 5% carbon dioxide atmosphere in a dessicator. After 3 h, 500 μ l of cold MEM was added to each sample; the cells were spun down and the supernatant removed. Cells and supernatant were then counted separately on a Packard Autogamma scintillation spectrometer, and the results expressed as % ⁵¹Cr release.

Excellent ⁵¹Cr release with good sensitivity to inhibition by antibody occurred at spleen cell to CRBC ratios of 200:1 and RACA concentrations of 1/25,000, and these concentrations were used in all studies discussed here. Maximum killing usually ranged between 30% and 60% ⁵¹Cr release, with background ⁵¹Cr release of 0.5–3.0%. The alloantisera tested are conventional anti H-2 antisera, with good titres in complement

Fig. 1 The specificity of the CIA test. Various sera were incubated with BALB/c (H-2^d) or CBA/H (H-2^k) spleen cells (2×10^6) plus RACA (1/25,000) and CRBC (10^4) for 3 h. The reactions of the three anti H-2^d sera against BALB/c are very strong, whereas the anti H-2^k and anti H-2^b sera do not inhibit. The reaction of the anti H-2^k serum with CBA/H is similarly very strong. Serum 'b anti d', C57Bl6 anti BALB/c, reacts with CBA/H as would be predicted by public specificities shared by H-2^k and H-2^d. *a*, BALB/c effectors; *b*, CBA/H effectors. ○ 'NMS': Normal BALB/c serum; ● 'anti k': BALB/c anti CBA/H; △ 'anti b': (CBA/H × BALB/c) F₁ anti C57 Bl6; ▲ 'b anti d': C57Bl6 anti BALB/c; □ 'k anti d' No. 1: CBA/H anti P815Y; ■ 'k anti d' No. 2: CBA/H anti BALB/c.

mediated microcytotoxicity (up to 1/1000).

Many mouse alloantisera show a powerful specific inhibitory effect on cell-dependent antibody-mediated lysis of CRBC by spleen cells (Fig. 1). The effect of normal mouse serum, irrelevant antiserum or antiserum directed against specificities of the effector cell on ⁵¹Cr release are shown in Fig. 1. The killing by BALB/c spleen cells (H-2^d) is virtually eliminated by anti H-2^d antisera, but is only weakly inhibited by normal mouse serum, anti H-2^k serum, or anti H-2^b serum. Similarly, killing by CBA/H spleen cells (H-2^k) is strongly inhibited by anti H-2^k serum, but only weakly inhibited by anti H-2^d and anti H-2^b serum or by normal mouse serum. The exception, 'b anti d', anti H-2^d raised in C57Bl6 mice (H-2^d), reacts with CBA/H spleen cells in a manner predictable on the basis of public specificities shared between H-2^d and H-2^k (ref. 6). When allowance is made for this predictable cross-reaction, and when compared with the weak inhibitory activity of any mouse serum, the CIA is thus highly specific. The weak inhibitory activity of normal mouse serum and of irrelevant antiserum is similar to that noted in other systems⁷.

The specific inhibitory activity can be absorbed out (Fig. 2). Anti CBA/H serum which had been absorbed $1 \times$, $2 \times$, or $3 \times$ against 3×10^7 CBA/H spleen cells was assayed for its ability to inhibit killing by CBA/H spleen cells (Fig. 2a). One absorption produced a dramatic decline in the inhibitory activity, with further decline after each subsequent absorption. The cells used for absorption were resuspended and washed thoroughly and then assayed for their activity as effector cells (Fig. 2b). The first absorption leaves the cells used for this purpose with greatly reduced killing capacity, and each successive absorption reduces the killing capacity of the absorbing cells less. Thus, the inhibitory activity of the alloantiserum is absorbed out, and the absorbing cells become inhibited in their killing capacity. Additional experiments indicate that this inhibition of killing capacity lasts for at least 24 h when the antibody-coated effector cells are washed and incubated at 37°C.

We therefore feel that the CIA detects a specific, absorbable activity which is probably alloantibody in nature. We investigated whether this antibody is directed towards the H-2D and H-2K 'serologically-defined' specificities, or towards other H-2 or non H-2 antigens by testing an anti H-2^d serum and an anti H-2^k serum against various congenic mouse

strains, with a C57Bl/10 Sc Sn (B10) background, differing only in all or part of the H-2 region (Fig. 3). Here the specificity controls, BALB/c and CBA/H, show that the reaction is completely specific. The anti H-2^k serum causes strong inhibition of B10.BR, B10.AKM and B10.A, each of which shares part or all of its H-2 region specificities with H-2^k. Similarly, anti H-2^d serum inhibits killing by B10.A and B10.AKM cells which have part of their H-2 regions from H-2^d (B10.A) or from H-2^a (B10.AKM), which has many specificities in common with H-2^d. The weak reaction of both anti H-2^d and anti H-2^k sera with B10 cells is expected on the basis of shared public specificities.

While complete understanding of the specificities involved remains to be established, we believe that 'serologically-defined' H-2 specificities can explain most of the inhibitory activity of these alloantisera.

The mechanism of this inhibition is under study. The absence of complement from the medium, the high titres of inhibitory activity in the sera (1/3,500 or more) and cell counts made after many hours of incubation seem to make cell death or agglutination unlikely mechanisms. Damage to a small sub-population of cells, the actual effector cells, is impossible to rule out at present because these cells are morphologically unidentifiable. On the basis of current knowledge of the killing systems mediated by antibody and effector cells^{8,9}, the most likely mechanism is that 7S antibody attached to a surface antigen on either the effector cell or an adjacent cell, blocks the receptor by means of the Fc portion of the antibody, perhaps in the form of an immune complex. This would be in agreement with present concepts of the binding of immune complexes by the Fc receptor^{10,11}.

We cannot explain the dichotomy between the ability of mouse spleen cells to lyse antibody-coated CRBC and their apparent inability to lyse alloantibody-coated allogeneic cells. One report¹² documents the cell-dependent lysis of YAC and P815Y tumour cells coated with antibody raised against YAC tumour cells in CBA mice but the possibility that this is antitumour activity, and not anti H-2 activity, which is mediating this lysis has not been investigated*. If most alloantisera in mice cannot mediate cell-dependent target cell destruction, then what is the importance of the interaction of these antibodies

Fig. 2 The effect of absorption of serum with specific cells. 1 ml of BALB/c anti CBA/H (1/50) was absorbed for 30 min at room temperature with 3×10^7 CBA/H spleen cells, once, twice, or three times. The inhibitory activity was then assayed against fresh CBA/H spleen cells at serum concentration 1/125. Similarly, the cells used for the absorption were resuspended and their cytotoxic activity was assayed to see if they had been inhibited. *a*, The inhibitory activity is greatly reduced after only one absorption; *b*, the cytotoxic activity of the cells used for the absorption is greatly reduced. All studies done for 3 h at 37° C at effector: CRBC ratios of 200:1 and RACA concentration 1/25,000. Absorption with BALB/c cells (not shown) has no effect.

Fig. 3 Typical study of the association of inhibitory activity in alloantisera with H-2 antigens. Spleen cells (2×10^6) were incubated with RACA (1/25,000) and chromium labelled CRBC (10^4), in the presence of 1/50 normal mouse serum, anti H-2^d serum (CBA/H anti BALB/c) or anti H-2^k serum (BALB/c anti CBA/H). The controls with no added normal mouse serum are indicated (—●—). Complete specificity is shown on the basis of the reactions with BALB/c and CBA/H. The strong reactions of both sera with B10.A, and of anti H-2^k with B10.BR and B10.AKM are attributable to private and public specificities. The reactions of both sera with B10, and of anti H-2^d with B10.AKM, can be attributed to public specificities alone. The table indicates the source of the genetic material for this region in the H-2 complex. 'd', Derived from H-2^d; 'k', derived from H-2^k; 'b', derived from H-2^b; and 'q', derived from H-2^a (ref. 13).

with the Fc receptor of the effector cell? Perhaps the lack of killing of the target cell in such interaction in mice permits enhancement phenomena to occur more readily.

Finally, the CIA is negative with some sera that are weakly positive in complement-dependent lysis. This could be explained by differences in antibody classes: complement-dependent lysis will detect 7S and 19S antibody, whereas it seems likely the Fc receptor will be blocked only by 7S antibody. The sera which are positive in the CIA usually have titres higher than their complement-dependent cytotoxic titre. The CIA thus provides an important new alloantibody assay, independent of complement, for mouse immunogenetic studies, and also, as we shall report elsewhere, for immunogenetic studies in man.

P.H. is supported by an Ontario Department of Health Fellowship Grant. We are grateful to the Cancer Research Campaign and to the London Hospital Endowment Fund for support. Breeding pairs for congenic mice were provided by Dr Peter Demant. We wish to thank Dr J. A. Sachs and Miss K. Abbasi for H-2 antisera.

Inhibition and reversal of capping by cytochalasin B, vinblastine and colchicine

THE phenomenon of capping in lymphocytes¹⁻⁴ consists of the segregation of membrane components, specifically cross-linked by antibody or other ligand, at one pole of the cell, typically that surrounding the centrosome^{1,2}. Capping has been interpreted as resulting from a countercurrent flow of membrane components, in which the cross-linked patches are transported towards the centrosome region by interaction with cytoplasmic structures, while the unaffected parts of the membrane flow in the opposite direction^{1,2,5}.

This interpretation indicated a possible role in capping of contractile microfilaments and microtubules. With the exception of a negative report⁶, cytochalasin B, which apparently impairs microfilament function⁷, was found to inhibit consistently, although in most cases only partially, capping of surface immunoglobulin (Ig) (refs 1, 3, and 8). Microtubule-affecting drugs, like colcemid and vinblastine, had no inhibitory effect^{1,8}. It has been suggested, however, that microtubules could be involved in the control of surface Ig movement, as the inhibition by con A of capping of surface Ig-anti-Ig complexes could be reversed by high doses (10^{-4} M) of vinblastine and colchicine^{8,9}. By studying the combined effect of vinblastine or colchicine and cytochalasin B on capping of surface Ig and con A receptors on mouse spleen lymphocytes, I have now found evidence indicating that both microfilaments and microtubules can play a direct role in capping.

Rhodamine-labelled rabbit anti-mouse immunoglobulin (rh-RaMIg), fluorescein-labelled sheep anti-mouse immunoglobulin (fl-SaMIg) and rhodamine-labelled rabbit anti-sheep immunoglobulin (rh-RaSIg) were prepared according to Cebra and Goldstein¹⁰. Con A (Miles-Yeda) similarly was conjugated to fluorescein¹⁰ (fl-con A) in the presence of 0.1 M glucose, 5×10^{-4} M MnCl₂ and 5×10^{-4} M CaCl₂ and purified by chromatography on Sephadex G-50. Only that fraction which strongly bound to Sephadex at pH 7.2., that is, which in a stepwise elution could be eluted between 0.01 M and 0.10 M glucose, was used. BALB/c spleen cells were incubated at 37° C in Leibovitz medium (L15) (Flow) containing 0.2% bovine serum albumin. This medium does not contain glucose, reducing the possibility of secondary effects due to inhibition of glucose transport by cytochalasin^{11,12}.

Vinblastine (5×10^{-5} M or less) had no effect on, or slightly enhanced the percentage of cells capped by rh-RaMIg, while cytochalasin B (10 or 20 μ g ml⁻¹) was partially inhibitory (Table 1). However, when cytochalasin B and vinblastine were used together, capping was virtually completely inhibited (Table 1), even after several hours. The same effect was obtained substituting colchicine for vinblastine (Table 2). The inhibition occurred with these drugs in a dose range of 10^{-4} – 10^{-6} M, at which they are known to affect microtubules^{13,14}. The antibody was distributed as random spots all over the inhibited round cells (Fig. 1a). Using a second label (rh-RaSIg) to stain the first fluorescent antibody (fl-SaMIg), it was found that several, but not all, of these spots were intracellular. The combined use

Table 1 Capping of surface Ig in the presence of vinblastine and cytochalasin B

	Sample	% caps
Experiment 1	1 Control	94
	2 Vinblastine 2.5×10^{-5} M	92
	3 Cytochalasin B 10 μ g ml ⁻¹	66*
Experiment 2	Cytochalasin B (18 μ g ml ⁻¹) present in all samples:	
	4 No vinblastine	84†
	5 Vinblastine, 5×10^{-5} M	8
	6 Vinblastine, 1×10^{-5} M	8
	7 Vinblastine, 5×10^{-6} M	13
	8 Vinblastine, 1×10^{-6} M	18
	Recovery (≤ 0.1 μ g ml ⁻¹ cytochalasin B):	
	5a Recovery from 5 (vinblastine, 5×10^{-5} M)	27†
	6a Recovery from 6 (vinblastine, 1×10^{-5} M)	78†
	7a Recovery from 7 (vinblastine, 5×10^{-6} M)	88†

Washed BALB/c spleen cells (2×10^7 cell ml⁻¹) filtered through glass wool, were preincubated 35 min (Experiment 1) or 90 min (Experiment 2) at 37° C in vinblastine or cytochalasin B as indicated. Each sample (20–40 μ l) was incubated with 20–40 μ l of rh-RaMIg, 15 min at 37° C and washed once by centrifugation (always in the presence of the drugs). Part of samples 5, 6, 7 were washed with medium containing vinblastine, but not cytochalasin B, and incubated for 15 to 30 min at 37° C, before examination. Samples with cytochalasin B in this and other experiments contained 0.25% dimethylsulphoxide which had no effect on capping. Cells were scored as 'caps' if the stain was detectable over no more than one half of the cell, irrespective of whether it was on the surface or pinocytosed.

* In other experiments the inhibition varied from 20 to 70%.

† Mainly pinocytosed label.

of cytochalasin and vinblastine therefore also blocked the polar accumulation of this pinocytosed material, which was not completely prevented by either drug alone. The cooperative inhibitory effect of these drugs on capping was even more apparent when the inhibited cells were resuspended in fresh medium containing vinblastine or colchicine, but no cytochalasin (< 0.2 μ g ml⁻¹, final concentration). The inhibition was reversed (Tables 1 and 2) and in less than 15 min all the label accumulated at one pole of the cell. Most of the label seemed, however, to be intracellular, that is, pinocytosed. The recovery was essentially complete in the presence of 10^{-4} M colchicine or 10^{-5} M vinblastine, incomplete at higher doses of vinblastine (Tables 1 and 2). If colchicine was removed and cytochalasin left in the medium, the recovery was incomplete (Table 2).

Cytochalasin B was even more effective on capping of con A receptors by fl-con A. At doses of 20–100 μ g ml⁻¹ this fl-con A

Table 2 Inhibition of capping of surface Ig by cytochalasin B and colchicine

	Sample	% caps
	1 Control	85
	2 Colchicine (10^{-4} M)	98
	3 Cytochalasin B 20 μ g ml ⁻¹	71
	4 Cytochalasin B (20 μ g ml ⁻¹) + 10^{-4} M colchicine	5
	5 Cytochalasin B (20 μ g ml ⁻¹) + 10^{-5} M colchicine	8
	6 Cytochalasin B (20 μ g ml ⁻¹) + 10^{-6} M colchicine	17
	Recovery (< 0.2 μ g ml ⁻¹ cytochalasin B):	
	4a Recovery from 4 (colchicine, 10^{-4} M)	83
	5a Recovery from 5 (colchicine, 10^{-5} M)	82
	Recovery (15 μ g ml ⁻¹ cytochalasin B):	
	4b Recovery from 4 (colchicine, $< 10^{-8}$ M)	30
	5b Recovery from 5 (colchicine, $< 10^{-9}$ M)	36

4×10^7 cells ml⁻¹ were preincubated at 37° C for 75 min in the presence of colchicine and cytochalasin B, as indicated, and then incubated with rh-RaMIg for 15 min at 37° C. Part of samples 4 and 5 were washed to remove either colchicine or cytochalasin B from the samples, and incubated for 15 min at 37° C (recovery).

Fig. 1 Inhibition and reversion of caps. The photographs were taken using a Leitz Ortoplan microscope equipped with Opak-Fluor vertical illumination (Leitz GmbH-Wetzlar). *a*, Cells stained with rh-RaMlg at 37° C in the presence of 20 $\mu\text{g ml}^{-1}$ cytochalasin B and 10^{-6} M colchicine (see Table 2); *b*, cells stained with 50 $\mu\text{g ml}^{-1}$ of fl-con A at 37° C in the presence of 20 $\mu\text{g ml}^{-1}$ cytochalasin B; *c*, cells stained for 10 min at 23° C with rh-RaMlg in the presence of 5×10^{-5} M vinblastine. Typical caps; *d*, the same, but incubated further for 35 min at 37° C with 20 $\mu\text{g ml}^{-1}$ cytochalasin B. Spotty rings, with some accumulation of label on one side of the cell.

preparation inhibited surface Ig capping^{3,8} only by 30–40% and formed con A caps in about 50% of the spleen cells in 10 min at 37° C. This capping was completely and reversibly inhibited by 10 min exposure to 10 $\mu\text{g ml}^{-1}$ of cytochalasin B, either in the presence or in the absence of vinblastine (Table 3; Fig. 1*b*). The change in cell shape from round to variably elongated which accompanied con A capping was also inhibited by cytochalasin.

Table 3 Inhibition of capping of con A receptors by cytochalasin B and vinblastine

Sample	% caps
Experiment 1	
1 Control	32
2 Vinblastine, 10^{-4} M	51
3 Cytochalasin B (10 $\mu\text{g ml}^{-1}$)	< 1
4 Vinblastine, 10^{-4} M + cytochalasin B (10 $\mu\text{g ml}^{-1}$)	0
Recovery (<0.15 $\mu\text{g ml}^{-1}$ cytochalasin B):	
3a Recovery from 3 (no vinblastine)	45
4a Recovery from 4 (vinblastine, 10^{-4} M)	36
Experiment 2	
5 Vinblastine, 10^{-5} M + cytochalasin B (10 $\mu\text{g ml}^{-1}$)	0
5a Recovery (cytochalasin B <0.1 $\mu\text{g ml}^{-1}$, vinblastine, 10^{-5} M)	52
5b Recovery (cytochalasin B 10 $\mu\text{g ml}^{-1}$, vinblastine $\leq 5 \times 10^{-5}$ M)	0

4×10^7 spleen cells were preincubated for 30 or 60 min at 37° C in vinblastine or cytochalasin B or in medium alone, then 90 μl of each sample were incubated with 10 μl of fl-con A (50 $\mu\text{g ml}^{-1}$ final concentration) for 15 min at 37° C. Part of samples 3, 4 and 5 were washed with medium free of cytochalasin or, respectively, vinblastine, as indicated, and incubated for further 30 min at 23° C (samples 3a, 4a) or 20 min at 37° C (samples 5a, b) before examination.

These findings demonstrate that cytochalasin-sensitive structures play an essential role in cap formation, and that microtubules are also somehow involved. The nature of the interaction between these structures is unknown. It is likely that the former corresponds to a cortical layer of microfilaments which interact directly with membrane elements⁷. The latter may interact indirectly with the membrane, perhaps through the mediation of microfilaments, and probably constitutes at least part of the internal cellular frame with respect to which mem-

brane movement occurs^{2,5}. As capping is not blocked by microtubule disruption, it seems likely that part of this frame and its polarity are preserved by other cellular structures. The different degree of inhibition by cytochalasin B on con A receptors and surface Ig capping could reflect differences in their interaction with cytoplasmic structures. It is also conceivable, however, that the function of these structures is affected only incompletely by cytochalasin B, to an extent sufficient to block cell movement, but not partial membrane displacements, which can occur also in the absence of cell movement^{2,5}. Differences in the extent of segregation achieved could then be quantitative and depend on the degree of cross-linking, size and number of the patches formed by a particular ligand.

Further evidence for the role of cytochalasin-sensitive structures, which indicates that they are involved in holding together the capped membrane, was provided by experiments in which preformed caps were 'reversed' into rings using cytochalasin. Cytochalasin B (10 $\mu\text{g ml}^{-1}$), either in the presence or the absence of vinblastine, reversed almost 90% of con A caps in 45 min at 37° C (Table 4), whereas little or no reversion was observed in rh-RaMlg caps. A large part of rh-RaMlg, however, was already pinocytosed within 10 min before the addition of cytochalasin, whereas, on the contrary, most of the capped con A remained on the surface. Repeating the experiment with

Table 4 Reversal of caps by cytochalasin B

	Time (min)	% caps
Experiment 1		
fl-con A caps (37° C, no vinblastine)	0	45
	45	6
Experiment 2		
rh-RaMlg caps (23° C, 5×10^{-5} M vinblastine)	0	91
	35	34

In Experiment 1, fl-con A caps were induced in 10 min at 37° C as described in Table 3 ($t=0$), then 10 $\mu\text{g ml}^{-1}$ of cytochalasin B were added and incubation continued, without washing, for 45 min at 37° C. In Experiment 2, spleen cells, preincubated for 2 h at 37° C with 5×10^{-5} M vinblastine, were incubated with rh-RaMlg at 23° C for 20 min. After washing, part of the sample was examined ($t=0$) and the rest incubated for 35 min at 23° C in the presence of 20 $\mu\text{g ml}^{-1}$ of cytochalasin B.

rh-RaMlg at 23° C and in the presence of vinblastine, which favours the formation of a true surface cap before the onset of appreciable pinocytosis, rh-RaMlg caps could be reversed by cytochalasin into spotty rings in about 60% of the cells (Fig. 1*b, c*; Table 4). Other (unpublished) data indicate that con A 'reversions' can also be induced by metabolic inhibitors, in agreement with an earlier report of Sällstrom and Alm¹⁵. These findings indicate that cytochalasin-sensitive structures are responsible for holding together the labelled patches into a single cap, even when these are not completely cross-linked by the ligand into a single complex; microtubules seem to be less important. On adding cytochalasin, the labelled patches are released and can mix again with the unlabelled membrane.

I thank Luciana Forni for rh-RaMlg, fl-SaMlg and rh-RaSIg.

Inhibition of surface capping of macromolecules by local anaesthetics and tranquillisers

IMMUNOGLOBULIN (Ig) molecules on the surface of B lymphocytes aggregate into a 'cap' when the cell is treated with anti-Ig¹⁻³. A similar process occurs with concanavalin A (con A) on neutrophil polymorphonuclear leukocytes (PMN)⁴. Capping occurs in two stages in both of these cell types^{4,5}: first, the ligand-receptor complexes aggregate into multiple clusters of variable size, leaving intervening bare membrane; and second, the clusters are swept into a single mass. Both stages are temperature-dependent (that is, they do not occur in the cold), but only the latter is energy-dependent (that is, clustering occurs but capping is inhibited on cells treated with metabolic inhibitors)⁴⁻⁶. The formation of clusters can be attributed to the ability of the ligand to cross-link receptors⁵; some form of membrane activity then sweeps the clusters into the cap. Capping can occur in the absence of cell locomotion^{4,7}, but if locomotion does occur the cap is found at the trailing end of the cell⁴. These aspects of capping have recently been analysed in detail^{4,7}.

We have now found that capping of con A on PMN, and of anti-Ig-Ig complexes on lymphocytes, is reversibly inhibited by local anaesthetics and tranquillisers which act as membrane stabilisers, characteristically able to inhibit membrane depolarisation⁸⁻¹¹.

Human PMN attached to glass coverslips⁴ were exposed to fluorescein-conjugated con A (100 $\mu\text{g ml}^{-1}$) in Hanks balanced salt solution (BSS) for 10 min at 4° C, washed in BSS, incubated (in the presence or absence of drugs) in BSS containing 10% foetal calf serum for 10 min at 4° C and then warmed to 37° C. In agreement with our previous observations⁴, fluorescence microscopy showed that, in the absence of drugs, approximately 95% of such cells developed caps of con A within 5 min; the PMN were motile and the caps were situated at the trailing end of the cell. Capping was inhibited in the presence of the local anaesthetics and tranquillisers; in addition, cell locomotion was suppressed. Testing with a range of doses (from 10^{-6} M to 4×10^{-2} M) established that complete inhibition of capping and locomotion occurred with 4×10^{-2} M Xylocaine, 10^{-3} M Nupercaine, 2×10^{-4} M chlorpromazine and 10^{-4} M trifluoperazine. Reversibility of this phenomenon was tested by washing away the drug just before warming to 37° C: capping was restored on approximately 95% of cells after treatment with Xylocaine, on 85% after Nupercaine, on 75% after chlorpromazine and on 50% after trifluoperazine.

The effect of Xylocaine on the redistribution of con A receptors on PMN was examined by electron microscopy of

shadow-cast surface replicas (using *Busycon canaliculatum* haemocyanin as a marker for con A¹²). Glass-attached PMN were exposed to con A (100 $\mu\text{g ml}^{-1}$) in BSS for 10 min at 4° C, washed in BSS, treated with haemocyanin (500 $\mu\text{g ml}^{-1}$) in BSS for 10 min at 4° C, washed in BSS and incubated (in the presence or absence of Xylocaine) in BSS containing 10% foetal calf serum for 10 min at 4° C. The cells were then warmed to 37° C for 10 min before fixation in glutaraldehyde and preparation of surface replicas⁴. As previously described⁴, electron microscopy of such specimens showed a random, dispersed distribution of con A on control cells labelled and fixed at 4° C; after warming to 37° C, the cells showed active locomotion and the con A quickly formed a single aggregate at the tail; if cell motility was impaired (for example, with cytochalasin B) capping occurred, but over the central region of the cell⁴. On PMN treated with Xylocaine, the con A aggregated into multiple, irregular, scattered patches at 37° C, but did not cap. Thus, capping was inhibited but not the temperature-dependent formation of patches.

We then studied the effect of these drugs on the capping of anti-Ig on lymphocytes. Mouse spleen cells were incubated with fluorescein-conjugated rabbit anti-mouse Ig (RAMG)⁵ for 15, 30 or 45 min at room temperature in the presence or absence of the drugs. After fixation in paraformaldehyde, the pattern of labelling was assessed by fluorescence microscopy. Capping was inhibited to different degrees by each drug (using the doses, mentioned above, which caused complete inhibition of con A capping on PMN) (Fig. 1). The inhibition by Xylocaine was complete. On the uncapped cells, label was distributed in multiple patches over the surface; such patches were small, in contrast to the large aggregates seen on metabolically inhibited lymphocytes⁵. Reversibility of this drug inhibition was tested in two ways: cells were exposed to the drug for 30 min, washed, and treated with RAMG for 30 min without the drug; or cells were treated with RAMG in the presence of the drug for 30 min, washed and incubated without RAMG or the drug for 30 min. Figure 2 shows that removal of the drug restored capping ability. This reversibility was particularly striking with Xylocaine.

Local anaesthetics inhibit membrane depolarisation by reducing sodium and potassium conductances⁹. This seems to follow displacement of calcium ions from binding sites in the membrane^{9,11,13,14}. In erythrocytes, such treatment leads

Fig. 1 Lymphocytes were collected from mouse spleens and purified by centrifuging on a Ficoll-Hypaque gradient; 5×10^6 cells (in 0.5 ml of Hanks BSS containing 1% foetal calf serum and the appropriate drug) were placed on tissue culture dishes; 50 μg of fluorescent RAMG was added and the suspension was incubated for 15, 30 or 45 min at room temperature, at which time an equal volume of 2.5% paraformaldehyde was added to stop the reaction. O, Control; □, 4×10^{-2} M Xylocaine; ▼, 10^{-3} M Nupercaine; ●, 2×10^{-4} M chlorpromazine; △, 10^{-4} M trifluoperazine.

Fig. 2 Reversibility of the inhibition produced by the drugs. Light hatching, Lymphocytes (5×10^6 in 0.5 ml) were incubated with the drug for 30 min in the presence of 50 μ g of fluorescent RAMG. (Note complete inhibition by Xylocaine). Coarse dots, Lymphocytes were incubated with the drug for 30 min, washed once and then incubated in fresh media containing RAMG for 30 min. Heavy hatching, Lymphocytes were incubated with the drug and RAMG for 30 min, washed once, and then resuspended in media free of drug and RAMG for 30 min.

to expansion^{15,16} and physical stabilisation¹⁰ of the membrane, providing protection against osmotic lysis¹⁷. Other effects of such drugs include the inhibition of several kinds of cell-to-cell interaction (platelet adhesiveness^{18,19}, cell fusion²⁰, leukocyte adherence to endothelium²¹), as well as inhibition of phytohaemagglutinin-induced lymphocytic transformation²². Our experiments indicate that they also affect the redistribution of membrane-bound ligands. Whether this is due to 'molecular packing' induced by the burying of drug molecules within the membrane⁸, or distortion and expansion of membrane protein¹⁵, or some other intrinsic membrane derangement is not clear. Because the movement of patches into caps may depend on cytoplasmic influences (such as an intact metabolism, and a colchicine-sensitive system and (or) cell locomotion)⁴⁻⁷, another possibility is that the drugs affect cytoplasmic constituents. Thus, the immobilisation of PMN during drug exposure (also reported for procaine-treated fibroblasts²³) may be due to an inhibition of release of internal calcium causing an inability to activate the contractile process²⁴. In addition, Xylocaine has been reported to cause a reversible disappearance of microtubules in rabbit vagus nerve²⁵. This may have relevance to recent data from this laboratory showing that capping can occur with a cross-linking ligand in the absence of cell movement, but only if a colchicine-sensitive system is intact^{4,7}.

Increased sensitivity of cell-free protein synthesis to double-stranded RNA after interferon treatment

NATURALLY occurring and synthetic double-stranded RNAs (dsRNAs) are interferon inducers¹. They inhibit protein synthesis in animal cells² and cell-free systems³⁻⁵. It is intriguing, therefore, that interferon treatment renders cells more sensitive to the toxic effects of dsRNA⁶, particularly as viral dsRNA may be involved in the replication of RNA viruses and has been isolated from DNA virus-infected cells⁷. Accordingly, the production of viral dsRNA in response to infection could bring about a general inhibition of protein synthesis in the interferon-treated cell, as is indeed observed in interferon-treated, vaccinia virus-infected mouse fibroblast L cells^{8,9}. The cell dies but little virus is produced: an effective way of limiting a natural infection.

Here we report an interferon-induced increase in the sensitivity of virus protein synthesis to inhibition by dsRNA in cell-free systems from interferon-treated L cells. Previously, we showed a similar enhanced inhibition of protein synthesis in such systems in response to infection with vaccinia or encephalomyocarditis (EMC) virus^{10,11}. The possibility that, in accord with the above hypothesis, this enhanced interferon-mediated inhibition of protein synthesis seen after infection is triggered by the synthesis of very small amounts of viral dsRNA is discussed.

The cell-free extracts used throughout were crude post-mitochondrial supernatant fractions from uninfected L cells. They were neither preincubated to lower endogenous incorporation nor passed through Sephadex to reduce the pool of cold amino acids. With such systems, a two to five-fold stimulation of amino acid incorporation in response to added EMC RNA as message is routinely observed and this stimulation is normally only slightly inhibited ($\leq 30\%$) by treatment of the cells with low doses (≤ 300 reference or 30 effective units ml^{-1} , see legend to Fig. 1) of interferon¹⁰. It is known that the added EMC RNA is translated correctly in these systems to yield EMC-specific polypeptides, initiation occurring at a single major site as in the intact EMC-infected cell¹²⁻¹⁶.

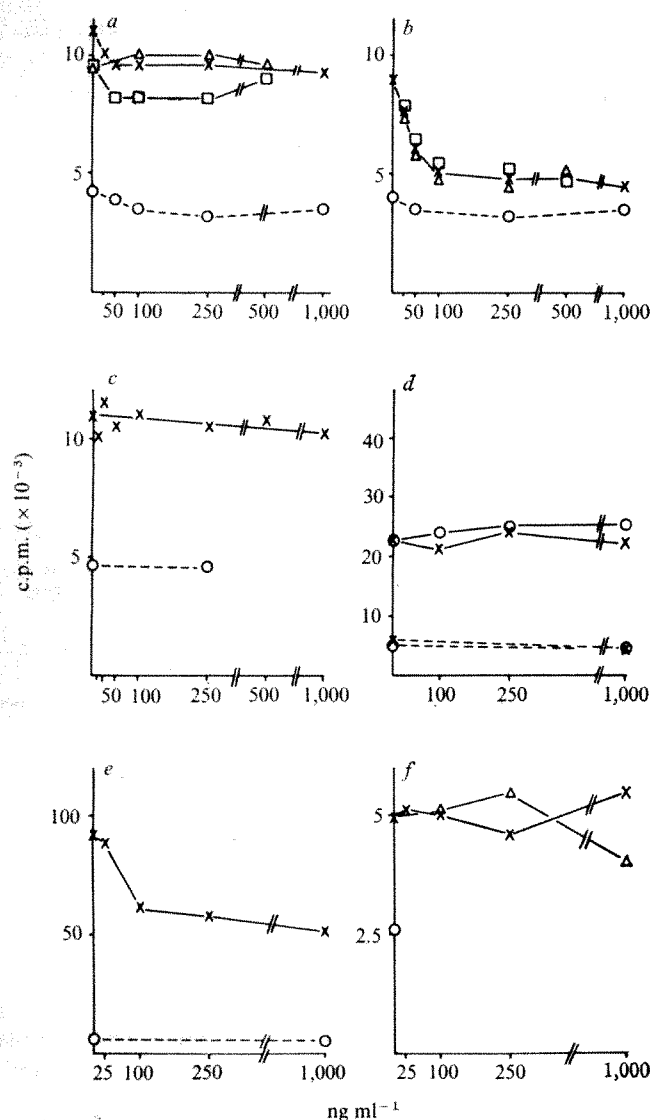

Fig. 1 Sensitivity of various cell-free systems to dsRNA and DNA. Crude postmitochondrial supernatant fractions were used throughout. The extracts in *a*, *b*, *c*, *d* and *f* were from L cells, that in *e* from Krebs cells. Interferon pretreatment of the cells was with 200 (*b*) or 300 (*d* and *f*) units ml^{-1} . The interferon concentrations throughout are in International Reference units based on the NIH standard. Ten reference units were equivalent to approximately one effective unit in reducing the yield of EMC by 50%. The heat-inactivated interferon (*c*) was at a concentration equivalent to 300 units ml^{-1} before inactivation: the heat treatment (60°C for 20 min) was just sufficient to destroy its antiviral activity. *a*, Control; *b*, endogenous amino acid incorporation \pm increasing amounts of reovirus dsRNA (O); EMC RNA-stimulated incorporation \pm reovirus (\times) and *P. chrysogenum* (\square) dsRNAs or poly(I)·poly(C) (Δ). The abscissa in all cases gives the range of final concentrations of the dsRNA, poly(I)·poly(C), or (in *f*) DNA in the assay. *c*, Heat-inactivated interferon; endogenous (O) and EMC RNA-stimulated (\times) amino acid incorporation \pm reovirus dsRNA. *d*, Endogenous (---) and poly U-stimulated (—) ^3H -phenylalanine incorporation \pm poly(I)·poly(C) with extracts from interferon-treated (\times) and control (O) cells. *e*, Krebs cell-free system; endogenous (O) and EMC RNA-stimulated incorporation (\times) \pm reovirus dsRNA. *f*, Endogenous (O) and EMC RNA-stimulated incorporation with extracts from interferon-treated L cells \pm calf thymus (Δ) and adenovirus (\times) DNA. The interferon pretreatment of the cells, the preparation of the cell-free extracts and their assay \pm EMC RNA or poly(U) have already been described¹³. The ordinates give the ^{14}C -amino acid (mixture) or ^3H -phenylalanine incorporation (in c.p.m. $\times 10^{-3}$ per 50 μl assay)¹³. Mouse L cell interferon purified by affinity chromatography²¹ ($\geq 5 \times 10^7$ units per mg protein) from Dr K. Paucker was used in most experiments. Electrophoretically purified interferon ($> 10^7$ units per mg protein) was from

MRE Porton, England. To check the effectiveness of the interferon treatment, samples of the cells used to prepare the extracts in these experiments were plated as monolayers, infected with 4–10 plaque-forming units per cell of EMC and the virus yield after 17 h at 37°C was assayed by haemagglutination. Reovirus dsRNA was from Dr J. J. Skehel, *P. chrysogenum* virus dsRNA²² from Dr R. A. Cox and adenovirus DNA from Dr W. C. Russell. Poly(I)·poly(C) lot 8, Control No. 11-8-321) and poly(U) were from Miles-Seravac (Pty) Ltd, Maidenhead, Berkshire, England.

In such cell-free systems from interferon-treated L cells the translation of added EMC RNA was markedly inhibited (50–90%) by reovirus and *Penicillium chrysogenum* phage dsRNAs and by poly(I)·poly(C) (Fig. 1*b*). These dsRNAs had much less effect on the corresponding untreated systems (Fig. 1*a*), on endogenous incorporation (Fig. 1*a* and *b*) or on the translation of poly(U) (Fig. 1*d*). The insensitivity of the untreated L cell system could be analogous to that of the chick fibroblast cell-free system¹⁷, but is in contrast to the rabbit reticulocyte and, to a lesser extent, the Krebs cell-free systems (Fig. 1*e*) (refs 3–5). The basis for this is not known.

On occasion, particularly on pretreatment of L cells with higher concentrations of interferon, we have observed some inhibition of the translation of EMC RNA in the cell-free system in the absence of infection or dsRNA. Such systems, however, still showed an enhanced sensitivity to dsRNA. The addition of dsRNA to a 50% inhibited system from cells pretreated with 500 reference units ml^{-1} of interferon for example, resulted in a virtually complete inhibition of the translation of the added EMC RNA.

The minimum concentration of dsRNA required for inhibition in cell-free systems from interferon-treated L cells (10–50 ng ml^{-1} , Fig. 1*b*) was higher than that required in the reticulocyte cell-free system (0.1–1 ng ml^{-1}) but was of the same order as that observed for the Krebs system¹ (Fig. 1*e*). No inhibition of incorporation was observed with similar concentrations (10–1,000 ng ml^{-1}) of adenovirus, calf thymus or SV40 DNA, rRNA, poly(I), poly(C) or alkali-digested poly(I)·poly(C) all of which gave data essentially identical to those shown in Fig. 1*f*. These results indicate that the inhibitory agent is indeed dsRNA and that the major inhibitory effect is likely to be on the initiation of polypeptide chains^{3–5} rather than on chain elongation as represented by the majority of endogenous incorporation in these systems. The rate and extent of EMC RNA-stimulated incorporation were both inhibited by poly(I)·poly(C) in cell-free systems from interferon-treated L cells (Fig. 2).

Fig. 2 Time course of amino acid incorporation in L cell-free systems from *a*, Control and *b*, interferon-treated (30 reference units ml^{-1}) cells. Endogenous (O) and EMC RNA-stimulated ^{35}S -methionine incorporation in the presence (\times) and absence (\bullet) of poly(I)·poly(C) (250 ng ml^{-1}).

Fig. 3 Dependence on interferon concentration of the enhanced sensitivity to dsRNA of EMC RNA-programmed cell-free protein synthesis. Ordinate: EMC RNA-stimulated amino acid incorporation in the L cell-free system in the absence (●) and presence (x) of 250 ng ml⁻¹ of poly(I):poly(C). Abscissa: interferon concentration used in treatment of the L cells¹³ before isolation of the cell-free extracts. Ten reference units (legend Fig. 1) of interferon were equivalent to approximately 1 effective unit. Accordingly, here EMC virus growth was inhibited by 30, ≥97 and ≥97% when assayed (legend Fig. 1) in samples of these cells exposed to 3, 30 and 300 reference (0.3, 3 and 30 effective) units ml⁻¹, respectively, of interferon.

The inhibition was relatively independent of extract concentration and was observed at all concentrations of EMC RNA tested.

An important consequence of these results is that in any experiment involving a comparison of the translation of different viral and host mRNAs in cell-free systems from interferon-treated cells, it will be necessary to consider the possible effect of even very small amounts of intrinsic or contaminating dsRNA structures.

The enhanced sensitivity to dsRNA has been seen with many cell-free extracts from eight different batches of L cells exposed to 10–500 reference (1–50 effective) units ml⁻¹ of four different preparations of highly-purified mouse interferon (>10⁷ reference units per mg protein) from two different laboratories. A dose response curve is shown in Fig. 3. Cell-free systems from L cells pretreated with interferon inactivated with respect to antiviral activity by heat (Fig. 1c) or trypsin treatment were insensitive to dsRNA. In addition, interferon treatment of Krebs cells of the line in use in this laboratory, which are very insensitive to interferon, did not enhance the sensitivity of EMC RNA translation in the cell-free system to dsRNA (data not shown).

The increased sensitivity to dsRNA reported here for cell-free systems from interferon-treated L cells raises the possibility that the enhanced inhibition of translation seen in cell-free systems from interferon-treated, vaccinia¹⁰, EMC¹¹ and mengo¹⁸ virus-infected L cells is triggered by the synthesis of small amounts of viral dsRNA. The events observed in the intact interferon-treated, vaccinia-infected L cell are consistent with this^{8,9}: both host and viral protein synthesis are inhibited (although whether by the same or different mechanisms is not yet clear), the cell dies and little virus is produced. A similar sequence of events occurs although more slowly in the interferon-treated EMC-infected L cell¹¹ (M. Esteban, D. R. Tovell, and I. M. K.,

unpublished). Double-stranded RNA has been detected in extracts from vaccinia-infected cells⁷ and may play a part in the replication of RNA viruses such as EMC. It is still not clear, however, that dsRNA as such exists in the intact cell¹⁹ and our initial attempts to detect a dsRNA fraction inhibitory to protein synthesis in cell-free systems from interferon-treated, vaccinia-infected L cells have been unsuccessful (L. A. B. and T. Hunt, unpublished). A direct connection between the effect of dsRNA and of infection on protein synthesis in the interferon-treated cell, therefore, remains to be established, but the copurification of the antiviral and dsRNA toxicity-enhancing properties of interferon preparations²⁰ strongly suggests that they are related.

Our results demonstrate an enhanced sensitivity of protein synthesis to dsRNA which could play a part in determining the fate of interferon-treated cells after infection with a variety of different viruses, possibly reflecting a mechanism basic to interferon action. If nothing more, they indicate a basis for the enhanced toxicity of dsRNA in the interferon-treated cell and provide further direct evidence for an interferon-mediated change in the protein synthetic apparatus of the cell.

We thank Drs Tim Hunt and J. A. Sonnabend for useful discussion.

Excess males among siblings of Australian antigen carriers

REPEATED studies have shown that Australia antigen carriers tend to group in families and there is considerable evidence that susceptibility to chronic asymptomatic infection producing Australia antigen (Au, hepatitis B antigen) is inherited as an autosomal recessive trait¹⁻³. The occurrence of asymptomatic carriers of Au varies in different populations, ranging from 0.1% in the United States and northern Europe to 24% in the Melanesian population of the Lau people on Malaita, as measured by immunodiffusion⁴. The frequency of Au carriers is relatively high in Oceania and particularly high in Melanesian populations^{5,6}. If this trait is genetically determined, there would be a greater number of individuals who are either homozygous or heterozygous for the proposed recessive gene, *Au*¹, in populations where the trait is common. Blumberg has suggested that these individuals may possess a selective advantage in certain environments⁷.

In 1960, Dr William Davenport confirmed earlier observations concerning an excess of males on the island of Santa Cruz in the British Solomon Islands Protectorate. He suggested that this alteration in sex ratio might be the result of selection by an infectious disease (personal communication). Blumberg⁸ reported that there was a deficiency of male offspring of certain matings when one of the parents had Au, that is, that Au is related to alteration in sex ratio. Here we report finding an excess of males among siblings of Au carriers in a Melanesian population.

During July, August and September of 1973, the population of the 15 villages in Graciosa Bay, Santa Cruz Island, Eastern District, British Solomon Islands Protectorate (BSIP) was tested for Australia antigen by immunodiffusion. Eight hundred and fifty-two people, comprising more than 95% of the total resident population of all ages were bled from a finger or toe prick into capillary tubes. None of these people had overt hepatitis. The serum was separated from the red cells and tested in a seven hole pattern using rabbit anti-Australia antigen (A5 and 6) in the centre well and control serum, from an asymptomatic blood donor which contained the antigen, in the top and bottom wells. The plates consisted of 1.1% agarose in 8.2 veronal buffer and were read at 24, 48 and 72 h (ref. 9). A census of the people living in Graciosa Bay and their immediate families was compiled. This included the names and present location of the mother, father and live-born siblings of all residents.

The frequency of Au carriers was 4.8%. Forty-one individuals with Au were distributed in 35 groups of siblings. Three groups contained more than one carrier. The sex ratio of the siblings of Au positive individuals and matched negative controls are shown in Table 1. The controls were matched by sex and within one year of age and had no first degree relatives who were Au carriers. The first appropriate individual listed in the census after the Au carrier to be matched was accepted as the control. The analysis includes all live-born siblings regardless of subsequent death or absence from the village. The ratio of males to females among the Au carriers approaches 2:1. This excess of males among carriers has been observed previously¹⁰ and presumably is not dependent on any special conditions existing on Santa Cruz. The number of males per 100 females among the siblings of the control group is 98. The ratio of males to females among the siblings of Au carriers is 161:100. When these data are tested by Fisher's exact test (Table 2), the result indicates that the observed distribution is not likely to occur by chance. Thus, the observed sex ratio represents a significant excess of males among the siblings of Au carriers. This observation has important genetic, cultural and biological implications.

The report on the census of the population, 1970 by the Western Pacific High Commission, (BSIP) (ref. 11) contains

Table 1 Sex ratio of siblings of Au carriers and negative controls

	Total	Female	Male	No. of males per 100 females
Au carriers	41	14	27	193
Siblings of Au carriers	146	56	90	161
Siblings of Au negative controls	180	91	89	98

Table 2 Fisher's exact test (two-tailed)

	Female	Male	
Siblings of Au positives	56	90	$P = 0.0159$ this occurrence
			$P = 0.0364$ this occurrence or more extreme
Siblings of Au negatives	91	89	

considerable comment on the high incidence of males compared with females in the Solomon Islands, particularly in Melanesian populations. In 1970 there were 530 males per 1,000 Melanesians. There were 526 males per 1,000 in the 0-14 yr age group. The mechanism of this selection is obscure. It is reasonable to assume however, that males have had a reproductive advantage in Santa Cruz. Although there is an excess of males living on Santa Cruz, there are excess women available for marriage in the Reef Islands; these women are brought to Santa Cruz as brides. The keeping of concubines¹² has been practised until recently and there has been a high mortality among women of childbearing age in the Solomons¹¹, resulting in men frequently having more than one wife. In the Santa Cruz population, in matings which can produce Au carriers, there is apparently a sex related effect which reduces the number of live born female offspring. We suggest that because Australia antigen families have a higher proportion of males who have had a reproductive advantage and may be capable of transmitting the Au trait, the Au trait would tend to increase in the population resulting in the observed high frequency of both Au carriers and males in the Santa Cruz and possibly other Melanesian populations. The question of whether the mechanism of the transmission of the Au trait which results in family clustering is genetic or not is irrelevant to this model for Au carrier amplification.

Davenport has described trade relationships which have existed between the Outer Eastern Islands¹³. The one-way travel of women from the Reef Islands to Santa Cruz in exchange for bride prices consisting of red feather money and food, was basic to the economy and trade relationships of the entire island group. The shortage of women on Santa Cruz, due in part to the excess masculinity in Au families, must have enhanced this trade. The removal of women to Santa Cruz also reduced the population expansion in the Reef Islands which have limited resources for the support of a growing population. Thus, the economy of an entire island group may to some degree be affected by selective pressures which are apparently related to the interaction between genetic factors and the epidemiology of an infectious agent.

The mechanism of prenatal selection among siblings of Au carriers is not clear. It may be directly related to foetal mortality resulting from infections with Au or the infectious agent associated with Au, or it may be due to maternal rejection of infected foetuses. It could also be the result of developmental or maternal-foetal interactions which are only indirectly associated with the production of Au carriers.

We thank Dr H. Cohen of Princeton Laboratories for the antiserum and R. Dodd of the American Red Cross for the antigen used in this study. We acknowledge the assistance of C. B. Tanen and members of the British Solomon Islands

Adenyl cyclase stimulation by aspirin in rat gastric mucosa

ASPIRIN consumption is associated with gastric mucosal erosions^{1,2} and upper gastrointestinal haemorrhage³⁻⁵, and has been postulated as a factor in the development of chronic peptic ulcer^{6,7}. It has been reported to cause chronic gastric ulcer in rats⁸. There is, however, no real understanding of the mechanism of these injuries. Menguy *et al.*⁹ suggested that the damage to the gastric mucosa results from lack of energy (ATP) for cell function. The reported antagonism of cholera enterotoxin by aspirin in the rat intestine¹⁰ might have been mediated through the inhibition of adenyl cyclase. We have now found, however, that aspirin can stimulate the activity of this enzyme in rat gastric mucosa.

Male Holtzman rats (200–300 g) were fasted overnight and then given aspirin by stomach tube (150–300 mg kg⁻¹ body weight, homogenised in 1% methyl cellulose). Control rats were given an equal volume of 1% methyl cellulose alone. After an appropriate time (5 min to 5 h) the rats were killed and mucosa was removed with a glass microscope slide; this and all subsequent manipulations were done at 2°–4° C. A 10% w/v homogenate of the mucosal scrapings was prepared in Tris–Mg²⁺ buffer, pH 7.5, in an all-glass homogeniser. This was centrifuged at 1,000g, and the precipitate was used for all assays.

Adenyl cyclase activity was determined from the rate of formation of 3',5'-cyclic AMP from ¹⁴C-ATP, (Amersham/Searle) specific activity 1.03 mCi mmol⁻¹, according to a

Fig. 1 *a*, Short term (5–45 min) effect of oral aspirin (300 mg kg⁻¹ body weight) on rat gastric mucosal adenyl cyclase. Each point represents a mean \pm s.e.m. for three rats. Stimulation of adenyl cyclase becoming apparent within 5 min after oral administration. *b*, Long term (between 1–5 h) results. Adenyl cyclase activity is expressed as nmol cyclic AMP per mg protein, represented as bars. Each bar shows mean value of adenyl cyclase \pm s.e.m. (*n* is the number of rats). All values are highly significantly different from the control. Various dose schedules (75–300 mg kg⁻¹ body weight) of aspirin were tried and a dose of 300 mg kg⁻¹ of body weight was selected as the optimal dose. 150 mg kg⁻¹ aspirin gave comparable results after 30 min of oral administration.

modification of the procedure of Krishna *et al.*¹¹. Enzyme activity was expressed as nmol of 3',5'-cyclic AMP produced per minute per mg protein as determined by the method of Lowry *et al.*¹².

Gastric mucosal homogenate (1,000g precipitate) as described above was prepared from 24 rats, in six groups of four. Aspirin in methyl cellulose was added to the gastric mucosa of each of four rats at concentrations of 0.3, 0.6, 0.9, 1.2 and 1.8 mg per 0.38 ml of reaction mixture. Four mucosae treated with equal volumes of methyl cellulose served as controls. The rest of the procedure for measuring adenyl cyclase activity was as described above.

The effect of aspirin (300 mg kg⁻¹) became apparent 5 min after the oral dose (Fig. 1). Stimulation of adenyl cyclase was maximum 4 h after the oral dose and was significantly different from the control value, as shown by Student's *t* test (*P* 0.001). Results were also significantly different from control after between 1 and 5 h, but not significantly different from each other.

Figure 2 shows that there is a direct correlation between aspirin concentration and the degree of adenyl cyclase activity. The activity seemed to increase linearly with aspirin concentration up to 1.8 mg of aspirin in 0.38 ml of reaction mixture.

The report that aspirin counteracted the effect of cholera toxin on the intestine of rat¹⁰ suggested a decrease in mucosal adenyl cyclase activity, and a similar decrease was expected

Fig. 2 Effect of aspirin *in vitro* at various concentrations (0.3–1.8 mg per 0.38 ml of reaction mixture) on rat gastric mucosal homogenate (1000g precipitate) adenylyl cyclase activity. Each point represents a mean \pm s.e.m. of mucosae of four rats. A linear relationship between aspirin concentration and adenylyl cyclase activity is evident.

after administration of aspirin. Since cyclic AMP was shown to decrease gastric acid secretion^{13–15}, the lowering of adenylyl cyclase activity after aspirin might have explained the mechanism of injury by aspirin. But our experiments refute this contention. If one could correlate these findings and if one believes reports that cyclic AMP stimulates gastric acid secretion^{16–19}, the stimulation of adenylyl cyclase by aspirin may explain the mucosal injury. It is also possible that the stimulation exhausts the ATP stores⁹ quickly, thus causing mucosal injury.

Davenport^{1,2} demonstrated that aspirin damages the gastric mucosal barrier and causes hydrogen ion back diffusion, as judged by the development of hypoacidity in a gastric pouch after administration of aspirin. If one postulates^{13–15} that cyclic AMP inhibits gastric acid secretion, this may be another explanation for the hypoacidity seen after injury by aspirin.

Cyclic AMP, ATP and cell contact

DENSITY-DEPENDENT¹ or contact-inhibited² cells stop dividing when they reach confluency; however, transformed cells do not exhibit this type of growth control³. Several experiments suggest that adenosine 3',5'-cyclic monophosphate (cyclic AMP) is involved in regulating the cell division of cultured fibroblasts. The dibutyl derivative of cyclic AMP inhibits proliferation of transformed cells⁴, and the steady state levels of cyclic AMP in normal density-dependent fibroblasts are higher than the corresponding virus and spontaneous transformed cell lines^{5,6}. There are, however, discrepancies between experiments which have attempted to compare the cyclic AMP levels of logarithmically growing with quiescent, density-inhibited 3T3 cells. Experiments in our laboratory showed that cyclic AMP levels of 3T3 cells do not change over the cell density of 1×10^4 – 6×10^4 cells per cm^2 (ref. 5). These results have been confirmed by others using the same cell system⁷. Otten *et al.*^{8,9}, however, reported that cyclic AMP levels of logarithmically growing 3T3 cells are lower than those of confluent, quiescent cells; Heidrick and Ryan⁹ reported similar results using L cells.

In an attempt to reconcile those contradictory data, we have thoroughly investigated the relationship between cell density and the cyclic AMP levels of mouse 3T3 cells. We have also studied deoxyglucose transport and cellular ATP levels as possible density-dependent phenomena. Measurements were made at sparse cell densities (no cell–cell contact), after cell contacts were established and again after growth to a confluent monolayer. A critical membrane-mediated event seems to occur at the cell–cell contact state (before confluency), resulting in decreased glucose transport, decreased ATP and increased cyclic AMP. Such changes may prime the normal cell for eventual density-dependent growth inhibition. Transformed cells which do not exhibit regulated inhibition of growth show little change in these biochemical parameters when compared at the three cellular densities.

Swiss 3T3, 3T6 and PY3T3 cells (a gift of Dr Howard Green) and BALB 3T3 cells and SV3T3 cells (a gift of Dr G. J. Todaro) were routinely grown in Dulbecco's modified Eagle's medium supplemented with 10% calf serum (Colorado Serum Co.) and penicillin-streptomycin (100 U ml^{-1} and 100 $\mu\text{g ml}^{-1}$, respectively). Cyclic AMP was measured by Gilman's method¹⁰. Cells were prepared for assay by washing twice with phosphate-buffered saline (warmed to 37° C), then adding cold (4° C) 5% trichloroacetic acid (TCA). The TCA supernatant, obtained by centrifugation, was extracted five times with 5 volumes of water-saturated ether. Samples were then applied on small Dowex-1-formate columns (0.4 \times 3 cm) equilibrated with water. Columns were washed with 10 ml of water, and then cyclic AMP was eluted with 1 N formic acid. Eluates were lyophilised to dryness and redissolved in 0.2 or 0.4 ml of water. A sample of 0.05 ml was used for each cyclic AMP assay. Recovery of cyclic AMP, which was measured using ³H-cyclic AMP, was more than 90%, irrespective of total amounts of cyclic AMP (from 0.5 to 20 pmol). Another purification method using Dowex 50-H+ (ref. 8) was tested, but we found that the resin releases a substance which strongly inhibits cyclic AMP binding and so discarded this method. Internal standards and susceptibility to degradation by cyclic nucleotide phosphodiesterase were used routinely to verify that we were measuring cyclic AMP.

³H-deoxyglucose uptake was measured by the procedure of Martin *et al.*¹¹ after previous incubation at 37° C for 45 min in glucose-free Hanks salt solution. Cellular ATP was measured using a firefly lantern extract¹². Cells were washed three times with warm phosphate-buffered saline, and then cold 50% ethanol was added. The cells were scraped from the dish with a rubber policeman and mixed by a vortex. After at least 30 min in an ice bath, the suspension was directly used for determination of ATP. Protein was assayed according to Lowry *et al.*¹³.

Normal Swiss 3T3 cells grow in culture to 4×10^4 – 8×10^4 cells cm^{-2} at which density the cellular monolayer becomes quiescent as measured by DNA synthesis and cell division. The logarithmic phase of the growth cycle (under our laboratory conditions) extends to a density of 2×10^4 cells cm^{-2} ; at this density proliferation begins to plateau and eventually stops at 4×10^4 – 8×10^4 cells cm^{-2} . The relation between cell density and the intracellular cyclic AMP level is illustrated in Fig. 1. Since at least 10^6 cells were needed for each cyclic AMP assay, roller bottles were used for the lighter cultures and two to six 60- cm^2 plastic tissue culture dishes were used for the heavier cultures. Cells were plated at various concentrations (all other conditions being constant) and grown for 24 h. The cyclic AMP level and cell number were then determined. The basal level of cyclic AMP was low at sparse 3T3 cell density and began to increase at about 3×10^3 cells cm^{-2} (Fig. 1). Cyclic AMP then quickly increased to a stationary concentration that was twice the basal level of the sparse, noncontacted normal cells. This increase occurred during log phase growth at a density (3×10^3 cells cm^{-2}) that preceded confluency and the total cessation of cell division.

ATP levels of 3T3 cells at various densities were also investigated, and contrary to the results observed with the cyclic AMP levels, the amount of ATP per 10^6 cells decreased, reaching a minimum (about half of the maximum) after cell contact was established.

To preclude the possibility that cell volume changed as density increased, we measured the cell protein of 3T3 and transformed cell lines as they grew to confluency. Table 1 is a summary of that data and shows little effect of cell density on protein content of the cell lines studied. There were, however, large differences between mg protein per 10^6 cells of the various normal and transformed cell lines. Calculation of ATP concentrations using protein or cell number indicated differences in the ATP levels of normal and transformed cells.

PY3T3 and 3T6 cells had ATP levels similar to growing (precontact) Swiss 3T3 cells, but once the normal 3T3 cells touched and the ATP level decreased, there was a significant difference between the transformed and normal 3T3 cells. A similar trend was observed with the BALB mouse-derived normal and transformed cell lines. A previous report that growing 3T3 cells had slightly more ATP than quiescent 3T3 cells¹⁴ supports our present data, because the earlier comparison was made with cells that had established contact, and maximal differences between growing and confluent 3T3 cells were observed only with precontacted 3T3 cells.

Deoxyglucose transport followed a pattern similar to the ATP level in that uptake decreased after cell contact. Experiments using chick fibroblasts¹⁵, BALB 3T3 cells¹⁶, and mouse embryo cells¹⁷ have shown that deoxyglucose transport is inhibited at relatively low cell densities. Our experiments, using Swiss 3T3 cells, show that deoxyglucose transport is inhibited at a density as low as 2×10^3 cells cm^{-2} . Initial cell-cell contacts are established at 10^3 cells cm^{-2} . These data suggest that inhibited cellular transport is one of the first biochemical parameters affected by cell contact. Thus, the increase in cellular cyclic AMP may be a critical (although not necessarily primary) event and might, as previously suggested¹⁸, serve as a cellular signal which responds to the availability of crucial nutrients.

Increasing cyclic AMP levels could result from either a stimulated adenylate cyclase or an inhibited phosphodiesterase activity. The activity of adenylate cyclase, a plasma membrane enzyme, increases (both basal and adrenaline stimulated) as a function of 3T3 cell density¹⁹. But, Russell and Pastan²⁰ suggested that a membrane-associated cyclic AMP phosphodiesterase exerts a substantial effect on the cellular cyclic AMP level. The biological mechanism of the ATP change is unknown and any possible relationship between levels of ATP and cyclic AMP remains to be established.

These experiments settle the controversy concerning the role of cyclic AMP in the contact inhibition or density-dependency phenomenon. Otten *et al.*^{6,8} suggested that cyclic AMP mediates contact inhibition and that an increase of the basal level of cyclic AMP of the 3T3 cell occurred at confluency, but earlier we could detect no change in the basal level of cyclic AMP as 3T3 cells grew to confluence⁵. This controversy is now resolved by our finding that 3T3 cyclic AMP increases in response to cell contact which occurs at a density of 3×10^3 cells cm^{-2} . Little change in cyclic AMP level occurred at confluency. We missed the increase in cellular cyclic AMP before⁵ because the plating density of the 3T3 cells exceeded the cell density at which the cellular cyclic AMP increases from its initial level. Thus, we observed only a constant and increased cellular cyclic AMP level over the density of 10^4 cells per cm^2 to 6×10^4 cells per cm^2 . This change in the cyclic AMP level is critical in contact inhibition, as Otten *et al.*^{6,8} and Heidrick and Ryan⁹ concluded, although it does not, as they suggested, directly participate in or coincide with cessation of 3T3 cell division as cells become confluent. We suggest that this biochemical change is a prerequisite for contact inhibition of growth by showing that cyclic AMP

Table 1 ATP levels of several normal and transformed lines

Cell line	Protein (mg per 10 ⁶ cells)	Cell density (cells cm ⁻²)	ATP (nmol per 10 ⁶ cells)	ATP (nmol per mg protein)
Swiss-derived:				
3T3	0.48	1.5 × 10 ³ (precontact)	18.0 ± 1.8	37.5
	0.48	1.5 × 10 ⁴ (contact)	12.6 ± 1.7	26.3
	0.44	4.1 × 10 ⁴ (confluent)	10.9 ± 0.8	24.7
PY3T3	0.39	2.5 × 10 ³ (precontact)	14.5 ± 1.3	37.2
	0.43	2.0 × 10 ⁴ (contact)	14.4 ± 0.9	33.5
	0.41	5.0 × 10 ⁴ (confluent)	15.8 ± 0.8	38.5
3T6	0.37 ± 0.04	3.3 × 10 ³ (precontact)	11.6 ± 1.2	31.4
		4.4 × 10 ⁴ (contact)	12.0 ± 0.5	32.4
		1.1 × 10 ⁵ (confluent)	11.5 ± 0.5	31.1
BALB-derived:				
3T3	0.44 ± 0.04	1.4 × 10 ³ (precontact)	11.5 ± 0.5	26.1
		4.4 × 10 ⁴ (contact)	9.9 ± 0.2	22.5
		8.3 × 10 ⁴ (confluent)	8.7 ± 0.3	19.8
SV3T3	0.16 ± 0.02	3.0 × 10 ³ (precontact)	4.7 ± 0.2	29.4
		5.5 × 10 ⁴ (contact)	4.2 ± 0.3	26.3
		1.4 × 10 ⁵ (confluent)	4.3 ± 0.3	26.9

Protein determinations were performed on monolayer cultures at various densities after washing three times with phosphate-buffered saline. The cells were then solubilised in 1 N NaOH and protein was measured according to Lowry *et al.*¹⁴. ATP levels were measured by the method of Strehler and McElroy¹². Single points are the average of triplicate determinations. Variation is expressed as \pm s. d. when at least six separate determinations were done.

Fig. 1 Cyclic AMP levels (\square), ATP levels (\blacktriangle), and deoxyglucose transport (\circ) were measured as described in the text. These data points are the averages of triplicate determinations derived from one experiment.

increases at cell contact before the accumulation of 3T3 cells in a quiescent monolayer mechanisms.

Siefert and Paul²¹ found that cyclic AMP levels did not vary as a function of cell density; increased cyclic AMP was observed after 3T3 cells stopped dividing, regardless of density. They attributed the increase to the depletion of a serum factor necessary for continued proliferation. Our measurements were made 24 h after cell plating and were presumably not affected by serum or medium depletion. It is conceivable that both cell contact and serum factors could affect cyclic AMP levels, possibly through cell transport mechanisms.

These and other studies²²⁻²⁵ suggest that an important membrane-associated event in the contact inhibition or density-dependent inhibition of growth precedes the accumulation of normal cells in a confluent monolayer. Most likely, all membrane parameters that change as a function of normal cell contact—nutrient transport¹⁵⁻¹⁷, distribution of intramembranous particles²², membrane fluidity²³, plasma membrane enzyme activity²⁴ and cellular agglutinability²⁵—as well as the intracellular concentrations of cyclic AMP and ATP, signify important cellular changes culminating in inhibited cellular proliferation. But, each of these changes taken alone is probably not sufficient to induce true density-dependent inhibition of growth. Future studies should describe the membrane-associated signal which initiates these biochemical events and clarify relationships among the cellular processes that result in regulated cell division.

We thank Barbara Meyers and Sharron Gentry for technical assistance and Drs R. E. Scott and R. E. Barnett for discussions relating to unpublished data. This research was supported by grants from the American Cancer Society and the Leukemia Task Force.

α - and β -Retinyl acetate reverse metaplasias of vitamin A deficiency in hamster trachea in organ culture

DEFICIENCY of vitamin A causes a well-defined lesion, namely keratinised squamous metaplasia, in tracheobronchial epithelium¹. In this lesion, the normal columnar ciliated and mucus cells of the epithelium, which depend on vitamin A for their formation, are totally replaced by squamous cells which produce keratin. The mechanism of action of vitamin A in controlling this normal differentiation of ciliated and mucus cells is still unknown. We report here an *in vitro* system for studying this process, using organ culture of hamster tracheas in a chemically defined, serum-free medium. Growth of tracheas in this medium without vitamin A causes keratinised squamous lesions. Addition of vitamin A to the organ cultures after development of such lesions causes reversal of the process of keratinisation and replacement of the squamous cells by columnar ciliated and mucus cells.

It has previously been noted² that cultivation of mouse prostate in chemically defined medium without vitamin A resulted in squamous metaplasia of the prostatic secretory epithelium and that inclusion of vitamin A in the defined medium completely prevented this metaplasia. The addition of the vitamin A antagonist, citral, to tracheal organ cultures has also been reported to cause squamous epithelial lesions, but simultaneous inclusion of vitamin A in the medium prevented their formation³. In the present study, we have used vitamin A acetate (β -retinyl acetate) to reverse lesions of vitamin A deficiency, rather than prevent their formation. Moreover, we have found that the α -retinyl isomer of vitamin A (Fig. 1), previously believed to be an essentially inactive form^{4,5}, is also active (as α -retinyl acetate) in our *in vitro* test system.

Syrian golden hamsters were maintained from birth on a diet deficient in vitamin A (ref. 6) (General Biochemicals, Chagrin Falls, Ohio). The animals were weaned at 21 d and killed at 30–33 d. At this time the hamsters were still gaining weight and did not yet show signs of severe vitamin A deficiency; the tracheal epithelium was generally low columnar

Fig. 1 Structures of (a) β and (b) α -retinyl acetate. The double bond in the 5-6 position of the cyclohexene ring of the naturally occurring β -isomer has been shifted to the 4-5 position in the α -isomer.

or cuboidal, with patches of squamous metaplasia only rarely found. The animals were randomly grouped for treatment, and their tracheas were removed by sterile technique. Each trachea was opened from the larynx to the carina along the membranous dorsal wall and placed into a 60×15 mm culture dish containing 2 ml of medium (CMRL-1066), (ref. 7); with crystalline bovine insulin, $1 \mu\text{g ml}^{-1}$; hydrocortisone hemisuccinate, $0.1 \mu\text{g ml}^{-1}$; glutamine, 2 mM; penicillin, 100 units ml^{-1} ; and streptomycin, 100 $\mu\text{g ml}^{-1}$, added. All tracheas were cultured at 37°C for 4 d in the above medium, which does not contain vitamin A, serum, or any added protein other than insulin. All cultures were gassed with 50% oxygen, 45% nitrogen, and 5% carbon dioxide in a sealed box, which was gently rocked approximately 12 times min^{-1} to allow the trachea contact with both gas and medium. After 4 d, some tracheas were collected and the rest were cultured for an additional 6 d (before collection) in the above medium, also containing either a, no added vitamin A; b, β -all-*trans*-retinyl acetate (0.25 – $1.0 \mu\text{g ml}^{-1}$); or c, α -all-*trans*-retinyl acetate (0.25 – $1.0 \mu\text{g ml}^{-1}$). Properties of α -retinyl acetate were as follows: melting point = 41 – 42.5 ; by ultraviolet analysis $\lambda_{\text{max}}^{\text{EtOH}} = 311 \text{ nm}$, $\epsilon = 64,900$. No β -isomer was detectable in the α -retinyl acetate by nuclear magnetic resonance (NMR) analysis, which is capable of detecting as little as 0.2% β -retinyl acetate impurity; details of these analyses will be published elsewhere. β and α -retinyl acetate were dissolved in dimethyl sulphoxide and added freshly to the cultures at the time of media change, which was done 4 times a week. The final concentration of dimethyl sulphoxide never exceeded 0.1%; an equivalent amount was added to all control cultures. At the time of collection, all tracheas were fixed in 10% buffered formalin and embedded in paraffin. Cross sections of $5 \mu\text{m}$ were made through the mid-portion, stained with haematoxylin and eosin, and evaluated independently by two observers. The status of the epithelium was graded with respect to both the extent of squamous metaplasia and the presence or absence of keratin.

The results of over 200 tracheal cultures are shown in Table 1 and demonstrate the progression of keratinising squamous metaplasia in culture, as well as its reversal on addition of β - or α -retinyl acetate to the medium. After 4 d *in vitro* in medium without vitamin A, 56% of cultures exhibited some squamous metaplasia and 52% had produced keratin. After 10 d *in vitro* without vitamin A, further progression resulted in 84% of the cultures showing squamous metaplasia and 76% showing keratinisation. Addition of β or α -retinyl acetate to the cultures from days 4–10 effected a reversal of squamous metaplasia, so that less than 25% showed squamous metaplasia at 10 d. In contrast to the marked or severe squamous metaplasia seen in 32% of the cultures on day 4 (before treatment with vitamin A), only 3% of the cultures had this extent of metaplasia after 6 d of treatment with β -retinyl acetate. Further, the keratinisation present in 52% of cultures at day 4 was reversed by β -retinyl acetate treatment in every case; keratinisation was reversed in all but two cultures treated with α -retinyl acetate.

This organ culture method will facilitate the study of vitamin A analogues for their capability to effect normal differentiation of tracheobronchial epithelium. Since the assay measures the reversal of lesions caused by the absence of vitamin A, as well as inhibition of their formation, it seems that the effect of an analogue in this assay could not be attributable solely to a sparing or stabilising effect that it might have on endogenous vitamin A metabolism. Such a sparing effect on endogenous hormone metabolism has been suggested to explain the wide range of chemical structures which show insect juvenile hormone activity^{8,9}.

This assay clearly demonstrates that the α -isomer of vitamin A, previously reported to be almost inactive (as the aldehyde or alcohol) in supporting growth in the rat, has intrinsic ability to maintain normal differentiation in hamster tracheobronchial epithelium. This finding has been extended (unpublished results) in *in vivo* growth studies in our laboratory, which have demonstrated the capacity of α -retinyl acetate to sustain growth and life if given intraperitoneally to hamsters that would otherwise lose weight and die on a vitamin A-deficient diet. The potency of the α -isomer, however, is markedly less than that of the β -isomer in the hamster growth assay. It has also been shown that both α -retinoic acid and α -retinyl acetate have definite ability to promote growth in rats maintained on vitamin A-deficient diets¹⁰.

Our organ culture system may also prove useful to determine whether vitamin A and its analogues are capable of reversing squamous metaplastic or preneoplastic lesions of tracheobronchial epithelium that are induced by chemical carcinogens. Addition of excess vitamin A to prostatic organ cultures previously treated with 3-methylcholanthrene can suppress the hyperplastic and metaplastic response caused by this carcinogen in prostatic epithelium¹¹. It has also been shown that simultaneous administration of vitamin A to hamster tracheal organ cultures treated with benzo[a]pyrene can inhibit the hyperplastic response caused by the carcinogen¹²; however, in this case the inhibitory effects of vitamin A may be caused by inhibition of activation of the carcinogen¹³. In view of the hypothesis that human tracheobronchial epithelium

Table 1 Response of tracheal organ cultures to β -retinyl acetate or α -retinyl acetate

Treatment		Cultures with respective amounts of squamous metaplasia (%)				Cultures with keratin (%)	Total cultures
Day 1–4	Day 4–10	None	Mild	Marked	Severe		
No vitamin A	Collected day 4	44	24	17	15	52	46
No vitamin A	No vitamin A	16	32	28	24	76	62
No vitamin A	β -retinyl acetate	83	14	3	0	0	63
No vitamin A	α -retinyl acetate	76	14	8	2	3	59

Cultures were graded as to the percentage of their total epithelium showing squamous metaplasia on 4–8 cross sections from the middle of each trachea; if between 1% and 10% of the total epithelial length was squamous, it was graded as having mild squamous metaplasia; between 10–40% was graded as marked; and greater than 40% was graded as severe.

lium undergoes a prolonged series of metaplastic and pre-neoplastic changes before development of bronchogenic squamous cell carcinoma¹⁴, it would be of definite interest to know whether vitamin A and its analogues are capable of arresting or reversing the development of these lesions in organ culture.

We thank Hoffmann-La Roche for supplying α and β -retinyl acetate, William R. Henderson for assistance in feeding of special diets, Mary S. Baker for help with organ cultures in the early stages of these experiments, Betty J. Sanders for advice on histology, and Doris Overman for help with the manuscript. Eli Lilly and Co. and Upjohn Co. provided insulin and hydrocortisone.

Dynamics and function of vitamin A compounds in rat retina after a small bleach of rhodopsin

THE vertebrate visual pigment, rhodopsin, is located in the outer segment disks of the rod photoreceptor cells, and consists of a chromophore, 11-*cis* retinal, bound to a protein, opsin. During light adaptation, 11-*cis* retinal is isomerised to the all-*trans* configuration. All-*trans* retinal is then reduced to retinol by an oxido-reductase in the rod outer segments¹⁻⁴, and retinol diffuses to areas adjacent to the rod outer segments, where it is esterified to form retinyl esters⁵⁻¹². During dark adaptation rhodopsin is regenerated as essentially the reverse processes occur; however, it is not known in what form (retinyl ester, retinol, retinal) the chromophoric group is re-isomerised to the 11-*cis* configuration.

This understanding of the vertebrate visual cycle is based upon experiments in which high light intensities were used, and most or all of the rhodopsin was bleached. It is not known whether release, reduction and esterification of the chromophore occur after a smaller fraction of rhodopsin is bleached. Here, we report that these reactions also occur when 10% of the rhodopsin in a dark-adapted rat eye is bleached by a single light flash, and that some of the chromophore may be

re-isomerised to the 11-*cis* configuration without reduction to retinol.

Our technique for determining the *in vivo* proportions of vitamin A compounds consists of injecting radioactive vitamin A compounds into vitamin A-deficient rats, and then cochromatographing extracts of eye tissues with known marker compounds on thin layer chromatography plates¹³; the amount of radioactivity which cochromatographed with each marker compound was taken as an indirect measure of the amount of that compound in the extract. The method was used to study the distributions and proportions of vitamin A compounds in the eye during and after adaptation to high light intensities¹². In this study we determined the proportions of vitamin A compounds in rat eyes, one of which was kept in darkness, while the other was exposed to a light flash which bleached approximately 10% of the rhodopsin present.

One eye of a dark-adapted albino rat was exposed to a 20 ms flash of monochromatic light (504 nm) which had an intensity of 4.2 mW cm⁻². The flash apparatus consisted of a light source which focused light through an interference filter onto an optic fibre 7 mm in diameter; the other end of the optic fibre was mounted in front of a piece of doubly ground glass and an electronically-actuated mechanical shutter. At successive intervals after the light flash, both eyes were removed and the extracts of them were cochromatographed with marker vitamin A compounds (11-*cis* and all-*trans* retinal, retinol, retinyl ester) on silica gel thin-layer plates with a solvent of 8 parts ethyl acetate:92 parts hexane. The percentage of radioactivity in a vitamin A compound was obtained by dividing the amount of radioactivity which cochromatographed with that compound by the total amount of radioactivity which cochromatographed with all of the marker compounds¹². Subtraction of the percentage of radioactivity in a compound in the dark-adapted eye from the percentage of radioactivity in that same compound in the light-exposed eye yielded the results shown in Fig. 1.

By 5 to 10 min after the light flash, 11-*cis* retinal had decreased to its minimum, and *trans* retinal and retinol had increased. The 8% difference between the experimental and control eyes in the concentration of 11-*cis* retinal reflects a bleach of approximately 10% of the rhodopsin because 11-*cis* retinal, present only as the chromophore of rhodopsin, comprises 80% of the vitamin A compounds in the dark-adapted rat eye¹². Using the measurements of Cone¹³ for the attenuation

Fig. 1 Vitamin A compounds formed in the dark-adapted rat eye after a 20 ms flash of monochromatic light (504 nm). The ordinate scale is the difference between the percentage of radioactivity in a vitamin A compound in the flashed (experimental) eye and the percentage of radioactivity in that same compound in the dark-kept (control) eye. The abscissa scale is time after the light flash. Lines connect the mean values of four to six experiments; vertical lines indicate standard errors. □, Retinyl ester; △, retinol; ●, *trans* retinal; ○, 11-*cis* retinal.

and scattering of light by the rat cornea and lens and his measurements of the number of rods in the retina, we calculate that the rhodopsin of the entire retina should absorb 4.3×10^{13} light quanta. We can extract approximately 1 nmol of rhodopsin (6.0×10^{14} molecules) from the dark-adapted rat eye, and, assuming a quantum efficiency of bleaching of 0.65 (ref. 14), we should then expect to bleach about 5% of the rhodopsin by the light flash; considering the many sources of error in these measurements, this is in close agreement with our value of 10% inferred from the indirect detection technique.

By 10 min after the flash, *trans* retinal had started to decrease, retinol was at its peak concentration, and retinyl ester was increasing. As in adaptation to high light intensities, these results most probably reflect release of *trans* retinal from photolysed rhodopsin, reduction of retinal to retinol and esterification of retinol to fatty acids^{3,6-12}.

During 15 to 40 min after the flash there was regeneration of rhodopsin, as is evident from the increase in 11-*cis* retinal. During the same time, *trans* retinal decreased in concentration, but the concentration of retinyl ester remained stable. This result strongly suggests that some *trans* retinal was re-isomerised to the 11-*cis* configuration without being reduced to retinol. From 40 to 120 min after the flash, retinyl ester gradually decreased in concentration, while 11-*cis* retinal continued to increase; by 2 h after the flash, there was no longer any significant difference between the eyes in the proportions of vitamin A compounds. As in dark adaptation following extensive bleaching of rhodopsin, these results probably reflect hydrolysis of retinyl ester, diffusion of retinol into the rod outer segments, oxidation to retinal and isomerisation (at some point) to the 11-*cis* isomer^{3,7-12}.

In spite of the experimental variability, then, two important conclusions are suggested by these results: first, that release, reduction and esterification of the chromophore occur when 10% of the rhodopsin is bleached; and second, that isomerisation of the chromophore from the all-*trans* to the 11-*cis* isomer probably occurs as retinal. The latter conclusion is also supported by recent experiments with cattle retinae¹⁵ and rat retinae¹⁶.

As discussed elsewhere by one of us¹², the dynamics of vitamin A compounds in the eye (release, reduction and esterification of the chromophore and the reverse) may have one or some combination of three functions: (1) re-isomerisation of the chromophore; (2) minimising accumulation of reactive aldehyde groups and diffusional loss of retinol during light adaptation; and (3) confinement to and recycling of chromophore in the eye.

The present results argue against the first possibility—that re-isomerisation of the chromophore must occur in the retinol or retinyl ester form—since a 'short cycle' (release of all-*trans* retinal, re-isomerisation to the 11-*cis* form, and resynthesis of rhodopsin) seems to occur. To test the second possibility—that the 'long cycle' (reduction, esterification, hydrolysis, oxidation) is an overflow device which minimises accumulation of retinal and diffusional loss of retinol—would require determining whether a 10% bleach of rhodopsin is within the normal operating range of rod cells, and, if not, whether the long cycle occurs after even smaller bleaches of rhodopsin; the indications that some all-*trans* retinal is re-isomerised to the 11-*cis* form without being reduced to retinol might suggest that at still lower bleaching levels of rhodopsin, no reduction to retinol occurs at all. The third possible function—that of confinement and recycling of chromophore in the eye—seems especially important, not only during light adaptation, but also during the rod renewal process. In this renewal process, the rod disks (including rhodopsin) are synthesised *de novo* at the base of the outer segments, displaced apically, and finally digested by the pigment epithelium¹⁷⁻²⁰. Since the chromophore required for *de novo* synthesis of rhodopsin is not stored in the retina and much reach it through the pigment epithelium, the fraction of total vitamin A compounds in the eye which must be returned daily to the retina is $1/n$, where n is the number of

days required for complete rod renewal. Considering that rod renewal in the rat and monkey require, respectively, 9 and 12 d (refs 21, 22), the importance of a vitamin A transport mechanism is clear.

The chemical properties of vitamin A compounds and the locations of the enzymes mediating their interconversion seem especially well suited to such a function of confining the chromophore to the eye and transporting it within the eye. Thus, in addition to a reactive form, retinal, which forms visual pigment in the outer segments, there is a transport form, retinol, which is diffusible, penetrates cell membranes, and is formed in the outer segments; and there is a storage form, retinyl ester, which is nonreactive, nondiffusible and formed in areas adjacent to the outer segments.

This research was supported by the National Eye Institute of the US Public Health Service. We thank Hoffmann-La Roche for radioactive vitamin A compounds.

Difference in the cellular cholesterol to phospholipid ratio in normal lymphocytes and lymphocytic leukaemic cells

FLUIDITY of the fatty acyl chains of phospholipids in cell membranes is required for essential cellular activities, and the degree of fluidity can be influenced by cholesterol. Changes in the ratio of cholesterol to phospholipids can, therefore, affect the internal viscosity and molecular motion of lipids within membranes and this may function as a regulator in cell behaviour¹⁻⁴. Our studies of the surface membrane of normal lymphocytes and

Table 1 Cholesterol and phospholipid content of normal lymphocytes and lymphocytic leukaemia cells

Cell type	Total lipid (g $\times 10^{-12}$ per cell)	Cholesterol		Phospholipids		Cholesterol: lipid - P molar ratio

Standard deviations are given for the mean value of five or six determinations for each type of cell. Normal lymphocytes from the lymph nodes of 6-8-week-old animals were collected by teasing the tissue apart in a cold solution of tricine-buffered saline (pH 7.4) and allowing the pieces to sediment. The cells were then washed three times with cold tricine-buffered saline. Both ascites tumours were generally inoculated intraperitoneally at 10^5 cells per adult mouse, the cells collected 12-14 d later and washed three times in cold tricine-buffered saline. Lipids were extracted by chloroform-methanol (2:1, v/v), as described⁹. Stirring was continued overnight at 4° C and there was no significant increase in yield of lipid phosphorous by a second extraction of the residue obtained after filtration. The chloroform-methanol extracts were washed as described¹⁰ with 0.1 M KCl in the upper phase. Lipid phosphorous was determined by the method of Ames¹¹ after digestion of the sample with an ethanolic solution of Mg(NO₃)₂. Free cholesterol was separated from cholesterol ester by column chromatography on silicic acid, and the two components were then assayed separately by the FeCl₃ method¹². The cholesterol ester was only 0.5-1% of the total lipid.

* Assuming an average phospholipid molecular weight of 775.

lymphocytic leukaemic cells have shown that the surface membrane of the leukaemic cells has a lower rotational mobility of concanavalin A binding sites^{5,6}, and a higher fluidity of the lipid layer^{6,7}. We have now found that these differences in fluidity are associated with a difference in the cholesterol to phospholipid ratio in these cells.

Normal lymphocytes obtained from the lymph nodes of A and C57BL mice and CR/RAR rats all gave similar results. These cells contained 70-85% thymus-derived cells. Normal B lymphocytes were obtained from the lymph nodes of C57BL nude mice. The lymphocytic leukaemic cells used were from two thymus-derived mouse ascites tumours, one from A strain mice (YAC) used before⁵⁻⁷ and the second (EL4) from C57BL mice⁸.

The cellular content of total lipids, free cholesterol and phospholipids was determined in the different cells (Table 1). The leukaemic cells were larger than the normal lymphocytes, and contained a larger amount of total lipids, cholesterol and phospholipids per cell. In both types of cell, however, cholesterol was 5-6% of the total lipid, so that the normal lymphocytes and leukaemic cells had about the same amount of cholesterol per mg dry lipid. Phospholipids were 40-45% and 55-65% of the total lipids in normal and leukaemic cells, respectively, so that the normal lymphocytes contained less phospholipid. The proportion of phospholipids in the B lymphocytes from nude mice was about the same as that in the normal lymphocytes which contained 70-85% thymus-derived cells. The molar ratio of cholesterol to phospholipids (Table 1) was therefore significantly smaller ($P < 0.001$) in the thymus-derived leukaemic cells than in the thymus-derived or B normal lymphocytes.

Studies of leukaemic cells collected at different times after inoculation of 2.5×10^6 cells per animal have shown that cells with a decreased rate of cell division, 12-14 d after inoculation, had a similar cholesterol to phospholipid ratio to that of cells in the logarithmic phase of growth. The decreased cholesterol to phospholipid ratio that we have found in the mouse leukaemic cells that were larger than the normal lymphocytes, has also been observed with human lymphocytic leukaemias where the cells were smaller than the normal lymphocytes⁹. It is therefore unlikely that the difference in the ratio between normal and leukaemic cells is only due to a difference in cell size. Although there is a decrease in the cholesterol to phospholipid ratio, it is interesting that cholesterol is synthesised more rapidly in lymphocytic leukaemic cells than in normal lymphocytes¹³, presumably due to a loss of the feedback control that has been found with hepatomas¹⁴.

Our results indicate that the higher fluidity of the lipids in the surface membrane after malignant transformation of normal lymphocytes^{6,7} is associated with a decrease in the molar ratio of cholesterol to phospholipids, and not with a significant decrease in the amount of cholesterol per mg lipid. The larger cholesterol to phospholipid ratio in the normal lymphocytes can

explain the lower fluidity of their surface membrane lipids. We suggest that differences in this ratio may be involved in the regulation of growth and differentiation in normal and malignant cells.

Quantum conductance changes in lipid bilayer membranes associated with incorporation of acetylcholine receptors

CONSIDERABLE attention has focused on the isolation and characterisation of the nicotinic acetylcholine (ACh) receptor from electroplax¹⁻⁴. This receptor is identified by its ability to bind cholinergic ligands, and its molecular weight and amino acid content have been estimated^{5,6}. Similar extraction procedures have also been applied to nicotinic receptors from mammalian brain⁷ but it is not known whether the coupling of ACh to the receptor results in the opening of transmembrane channels, the activation of ionic carrier mechanisms or some other mechanism that modifies mem-

brane permeability. Little is known about the ionic permeability changes associated with the function of the single receptor. It has been reported⁸ that crude acetylcholinesterase (AChE) preparations from electroplax contain material capable of inducing transient membrane permeability changes in lipid bilayers in response to ACh or carbachol, but the relationship to ACh receptor function is unclear.

We wish to report discrete changes of conductance after the incorporation of an ACh receptor preparation into artificial lipid bilayers. These events were related to a unit conductance that is probably associated with some fundamental function of the receptor.

Receptors were extracted by modification of published affinity chromatography techniques that make use of the curaric properties of neurotoxins from elapid snake venoms⁴⁻⁶. *Naja melanoleuca* d-toxin (10 mg) was attached to 15 ml of Agarose A-15 (Biorad) beads by the cyanogen bromide reaction⁹⁻¹¹ and a typical receptor extraction then proceeded as follows. Twenty-five whole mouse brains were homogenised in 10 volumes of 0.05 M sodium phosphate buffer, pH 7.4, containing 0.1% Triton X-100 detergent. The particulate matter was removed by centrifugation at 10,000g for 30 min and the supernatant was passed through the toxin-Agarose gel. The gel was then washed with the same buffer-detergent solution plus 1 M NaCl to disassociate material bound by nonspecific ionic interactions, followed by receptor elution with a 0.0 to 0.5 M carbachol gradient in buffer-detergent. Protein determinations¹² indicated the possible presence of two protein peaks following exhaustive dialysis against 0.05 M phosphate buffer.

The ability of the original fractions from peak 1 (containing about 0.2 M carbachol from the gradient) to affect ionic permeability were examined in lipid bilayers as described earlier¹³. This involved a dilution of the original fractions by 400:1 to at most 25 ng ml⁻¹ of total protein and 5×10^{-4} M of carbachol in 100 mM NaCl on one side (*cis*) of the bilayer. The other side (*trans*) contained 1 M NaCl and the gradient thus formed allowed both sodium and chloride conductances to be estimated separately, depending on the polarity of the voltage clamp across the membrane. The chamber was made of a fluorochlorocarbon material (Kel-F) and contained a 1.4-mm hole over which the bilayer was spread. A Keithley 427 current amplifier was used to amplify the current changes sufficiently for detection on a strip-chart recorder. Clamp was maintained at + or -80 mV.

Fig. 1 Initial increase in chloride conductance after addition of receptor to *cis* side of bilayer. The final concentration of total protein was at most 25 ng ml⁻¹ with about 5×10^{-4} M carbachol.

Fig. 2 The same receptor preparation as in Fig. 1 except that 2.5×10^{-3} M of tubocurarine was added to the *cis* side of the bilayer. The scale is at 10 times higher resolution with (a) the chloride conductance and (b) the sodium conductance.

Under these conditions, two sizes of conductance changes were electronically detected with step increases of 2.4×10^{-10} mho (Cl^-) and 1.5×10^{-10} mho (Na^+) for large quanta and 5.9×10^{-11} mho (Cl^-) and 3.7×10^{-11} mho (Na^+) for small quanta. The initial conductance increase was monotonic and the chloride conductance recording is shown in Fig. 1. Addition of tubocurarine at competitive concentrations (2.5×10^{-3} M) seemed to slow the rate of occurrence of large quanta by about 30:1 and the smaller quanta became prominent (Fig. 2a (Cl^-) and b (Na^+)). A similar effect seemed to occur with addition of similar concentrations of atropine, although the nature of the studies made quantitation difficult.

When the carbachol was removed by dialysis of the receptor preparation against phosphate-detergent solution, the rate of occurrence of large quanta appeared to be reduced relative to the occurrence of small quanta. When the receptor was dialysed against phosphate alone, however, activity ceased, indicating that detergent was necessary to preserve the electrical properties of the molecular entity involved. In addition, if the receptor was eluted by a carbachol gradient in phosphate but in the absence of detergent, no electrical activity was detected when the preparation was incorporated into the bilayer. This occurred in spite of the detection of similar elution peaks. We had previously found that Triton X-100 alone did not affect our bilayer system at the concentrations used. Gel electrophoresis demonstrated the presence of one primary protein peak, although the possibility that the electrical activity is caused by another protein component cannot be excluded. Peak 2 showed qualitatively similar electrical activity.

The ionic selectivities of the large and small quanta and their relative size suggests that the large quanta represent an aggregate of four of the small quanta. This might be

Fig. 3 Conductance changes (Cl^-) for two runs after the receptor had been dialysed against 0.05 M phosphate buffer, pH 7.4, containing 0.1% Triton X-100 for 72 h with six changes of dialysate.

related to theories that the receptor can exist as a tetramer^{14,15}. We note that the electrical activity observed is consistent with the theory that Ach-mediated membrane permeability changes might occur by ionic channel gating.

We thank D. P. Botes for pure *Naja melanoleuca* d-toxin, and Drs J. R. Smythies and S. T. Christian for comments and suggestions. This research was supported by grants from the National Institutes of Health.

Opiate agonist-antagonist effects on Renshaw cells and spinal interneurons

ANALGESIC doses of morphine change the levels^{1,2} and release^{3,4} of acetylcholine from the central nervous system. At the single neurone level, however, little is known of the

effects of morphine on cholinergic transmission. On the only central neurones known to receive cholinergic endings, the Renshaw cells⁵, morphine administered electrophoretically from micropipettes has been shown to modify cell activity in several ways: to reduce the depressant action of glycine⁶, to increase the latency of action potentials evoked by a ventral root stimulus⁷ and to excite⁸.

To assess the relevance of these effects to the opiate syndrome⁹, we performed experiments with naloxone, a narcotic antagonist essentially devoid of agonist activity⁹. As a further test of specificity of effects observed with morphine, three morphinans were also studied: levorphanol, an active opiate; dextrorphan, an isomer devoid of narcotic activity; and levallorphan, a narcotic antagonist. The results indicate that excitation at nicotinic receptors for acetylcholine may be of relevance to the opiate syndrome.

Experiments were performed on 23 cats anaesthetised with pentobarbitone sodium. The spinal cord was prepared for stimulation and recording using conventional techniques¹⁰. Renshaw cells were located by the responses to stimulation of ventral roots. Extracellular recordings were obtained with the centre barrels of seven barrel micropipettes and the outer barrels contained the drugs to be ejected electrophoretically. These were: morphine SO_4 (70 mM), naloxone HCl (0.1 M), levorphanol tartrate (0.1 M and 50 mM in 100 mM NaCl), dextrorphan tartrate (0.1 M), levallorphan tartrate (0.1 M), acetylcholine Br (0.5 M), L-glutamate Na (0.5 M), L-aspartate Na (0.5 M), DL-homocysteate Na (0.2 M), glycine (0.5 M pH 3), γ -aminobutyric acid (0.5 M pH 3), atropine SO_4 (10 mM in 165 mM NaCl), dihydro- β -erythroidine HBr (10 mM in 165 mM NaCl), nicotine HCl (0.2 M), acetyl- β -methylcholine Cl (0.5 M).

Morphine (30-80 nA) excited 42 of 55 Renshaw cells tested. This effect was readily demonstrated on cells excited by low concentrations of acetylcholine (ejecting current less than 10 nA) and was not necessarily accompanied by bursts of firing. With cells relatively insensitive to acetylcholine, ejection of morphine with relatively high currents was more likely to produce bursts of action potentials with little rise in mean firing rate. Whereas the ejecting current of morphine required to produce cell firing was approximately ten times that of acetylcholine, much lower currents of morphine enhanced the excitant action of acetylcholine and/or an excitant amino acid. Excitation of a Renshaw cell by morphine acetylcholine and DL-homocysteate is shown in Fig. 1.

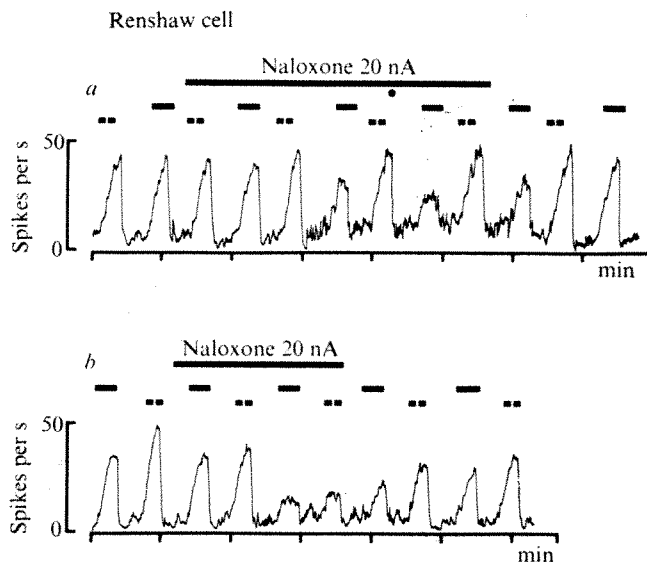

Fig. 1 The effect of naloxone on excitation of a Renshaw cell by, a, morphine (30 nA) (—) and DL-homocysteate (30 nA) (—) and, b, by morphine (30 nA) (—) and acetylcholine (7 nA) (—). The times of electrophoretic ejection of compounds are marked by horizontal bars above each record of cell firing.

Excitation by morphine was antagonised by naloxone. Ejecting currents of naloxone (10–30 nA) adequate to block the effects of morphine were usually without effect on cell firing but higher concentrations sometimes produced bursts of firing. Excitation by acetylcholine but not that by an amino acid was also reduced by naloxone. Figure 1 illustrates the differentiation between these two types of receptor by naloxone. Naloxone also reduced the excitant effect of nicotine but not that of acetyl- β -methylcholine on Renshaw cells, indicating a probable action at nicotinic receptors on these neurones. Dihydro- β -erythroidine (1–5 nA) readily reduced the action of acetylcholine on Renshaw cells and also reduced excitation by morphine. Atropine was a relatively poor antagonist of excitation of Renshaw cells by acetylcholine but again the action of morphine was also reduced in parallel with acetylcholine.

The other effects of morphine on Renshaw cells were not antagonised by naloxone. Naloxone acted like morphine in prolonging the latency of the initial action potentials of Renshaw cells in response to a ventral root stimulus but was without effect on the depressant action of glycine and GABA and did not modify the antagonism of glycine by morphine.

Morphine (5–100 nA) did not excite a sample of spinal interneurons located by firing in response to stimulation of peripheral nerves. Morphine (17 of 25 cells) and naloxone (10 of 12 cells) were depressants of these neurones and no antagonism of the action of morphine by naloxone was observed. This action of morphine has been previously reported¹¹ but the lack of antagonism by naloxone casts doubt on its relevance to the effects of systematically administered morphine.

All three morphinans tested reduced the sensitivity both to acetylcholine and an amino acid excitant of a proportion of Renshaw cells, an effect accompanied by a reduction in action potential amplitude. This was the only effect observed with dextrorphan (eight cells) and levallorphan (five cells) but with levorphanol, the active opiate, excitation was observed with five of twelve Renshaw cells. The reduction of effectiveness of all excitants is possibly a local anaesthetic effect¹² as these compounds are known to block conduction in squid axon¹³ and are more potent than morphine in this respect.

Concentration attained when drugs are administered micro-electrophoretically are unknown and therefore the relevance of effects observed with this method to those occurring after systemic administration can be difficult to assess. Nevertheless, as excitation by morphine at nicotinic receptors for acetylcholine was the only action of this alkaloid antagonised by naloxone the effect warrants further investigation. Studies of the distribution of opiate receptors in the brain of the rat based on the displacement of bound naloxone by active and inactive morphine-like compounds have found good correlation with the distribution of acetylcholine¹⁴. In this species electrophoretically administered morphine excited one half of the brain stem neurones sampled¹⁵ but no correlation with the effects of acetylcholine, noradrenaline or 5-hydroxytryptamine was observed.

Our experiments are being extended to cholinceptive cells in other regions of the central nervous system of the cat.

Lithium and the monoamine neurotransmitters in the rat hippocampus

ALTHOUGH the psychoactive properties and therapeutic value of lithium have long been recognised¹, relatively little is known about its mode of action in the central nervous system². This is partly due to the lack of a complete understanding of the biological basis of mental disorders and to the variety of biological functions that can be affected by lithium.

The putative monoamine neurotransmitters, noradrenaline, dopamine and serotonin have been implicated in such functions, and indeed lithium influences their metabolism in the brain^{3,4}. The precise distribution of monoamine-containing cell bodies, fibres and synaptic terminals has been well documented for several targets within the brain. Recently, the monosynaptic pathway between the catecholamine-containing pontine nucleus locus coeruleus (LC) and the hippocampus was studied physiologically and pharmacologically^{6,7}. In this pathway the iontophoretic application of noradrenaline suppresses spontaneous discharges of hippocampal pyramidal cells⁶ as does stimulation of the LC (ref. 7). These noradrenergic synapses in the hippocampus thus provide an ideal test system for the search for the mechanisms of psychoactive drugs in the nervous system. I describe here an attempt to elucidate a possible mode of action of lithium in the hippocampus. This was done by searching for possible interactions between the effects of iontophoretically applied lithium and several putative neurotransmitters as well as the electrical stimulation of the LC, on firing rates of hippocampal pyramidal cells.

I used male Zivic Miller rats (150–200 g) anaesthetised with halothane. Methods of recording and drug iontophoresis have been described elsewhere⁸. Briefly, spike discharges were recorded through the central barrel of a five-barrel micropipette. Three of the outer barrels contained lithium chloride (Li⁺, 0.1–0.2 M); acetylcholine chloride (ACh, Merck, 2.5 M); L-noradrenaline-HCl (Aldrich, 1 M); serotonin creatinine sulphate (Aldrich, 0.5 M) and γ -aminobutyric acid (GABA, Aldrich, 1 M). Each compound was ejected as cations, and retained with a negative holding current. The fourth outer barrel was filled with 3 M NaCl and ejected a continuous balancing current⁸. Stimulating electrodes were placed in the LC as described previously⁷.

The activity of thirty-five cells in the pyramidal cell layer of the dorsal hippocampus was monitored in eight rats. When applied iontophoretically (with a current range of

25–100 nA) Li^+ did not have a consistent direct effect on firing of hippocampal cells. Only three of the cells tested were slightly excited (120–140% of pre-drug rate) and two were slightly slowed (Fig. 1a), whereas the firing patterns or spike sizes of thirty other cells were not affected. Noradrenaline had a consistent and long lasting inhibitory action on spontaneous and Ach-enhanced hippocampal activity⁶. All fifteen cells tested were inhibited during application of noradrenaline (current range 50–100 nA applied in pulses of 15 s). In seven of the cells inhibition was reversibly antagonised during the concurrent application of Li^+ (Fig. 1b). In five more cases Li^+ (in 1.0 M concentration within the pipette) antagonised the cellular response to noradrenaline but no complete recovery was demonstrated even 10–30 min after application of Li^+ . Only three cells were unaffected by Li^+ .

The interaction between Li^+ and serotonin was tested in seven cells. Like noradrenaline, it was inhibitory with respect to spontaneous hippocampal cellular activity. Concurrent application of Li^+ for 2–3 min reversibly antagonised the inhibitory responses of three cells to serotonin. Four other cells were unaffected (Fig. 1a).

Fig. 1 Interactions between iontophoretic application of Li^+ , several putative neurotransmitters and LC stimulation. Hippocampal cellular activity in the pyramidal layer was integrated over 1-s intervals and recorded on an ink recorder. *a*, The effects of Li^+ on the responses to serotonin applied with an injection current of 60 nA at fixed regular intervals (bars). The concurrent application of Li^+ (with current of 100 nA), for 2–3 min caused a slowing of the spontaneous firing, but also blocked the response to serotonin. This response was reinstated 1–2 min after termination of Li^+ current. *b*, Same as in (*a*), with a different cell, Li^+ antagonised the response to noradrenaline with no noticeable effect on spontaneous activity. *c*, Li^+ effects tested against the iontophoretic application of GABA and stimulation of LC. Stimulation parameters: pulses of 0.1 ms, 0.4 nA, applied through a concentric stimulating electrode at a rate of 10 per s for 5 s. Li^+ had no effect on the response to GABA but there was an antagonism of the response to LC stimulation. Note the difference in time scale between (*a*), (*b*) and (*c*).

Among the other compounds tested, GABA exerted the most potent inhibitory action towards hippocampal activity and its effect was pronounced even with small ejection current (0–5 nA). But none of the responses of fifteen cells tested was affected by the iontophoretic application of Li^+ in the current ranges that proved to be effective for antagonism of the responses to noradrenaline and serotonin (Fig. 1c). Similarly, acetylcholine, a putative neurotransmitter in the hippocampus had an excitatory action which was not modified by the iontophoresis of Li^+ . The absence of interaction was noted in a number of cells, although no systematic tests were made.

Finally, electrical stimulation of the LC, the source of hippocampal noradrenergic fibres and terminals produce noradrenaline-like inhibition⁷ (Fig. 1c). In five out of six cells tested, LC stimulation was at least partially antagonised by concurrent iontophoretic application of Li^+ . This antagonism did not result, however, in a complete elimination of the response to LC stimulation. Since at least some of the

noradrenergic terminals on the recorded cell are probably remote from the pipette tip and may not be affected by the Li^+ ejected, a complete antagonism could be difficult to achieve.

Under the conditions of these iontophoretic experiments, there was a built-in control for defining the specificity of the effects of Li^+ . When Li^+ or the other compounds were not being ejected, they were retained in the pipettes with a continuous negative current. To neutralise the continuous retaining currents at the pipette tip between and during drug ejection, positive current, that is, Na^+ ions, was continuously ejected from the balance barrel. Therefore, in all cases, the effects of Li^+ were actually tested against the effects of Na^+ .

Lithium can exert its antagonistic action by changing the ionic balance in the recorded cell environment. Although this is considered to be a possible effect of Li^+ in living tissue^{8,10}, it is not likely to be the cause for the specific effect demonstrated here since spontaneous firing as well as GABA-induced inhibition were not modified in the recorded hippocampal cells. A more likely alternative mechanism for modification by Li^+ is the cyclic AMP system. It has been postulated that cyclic AMP mediates the electrophysiological response to noradrenaline in the rat cerebellum¹¹ and there is some evidence for such a case in rat hippocampus, where the phosphodiesterase inhibitor, papaverine, potentiates the response of hippocampal cells to noradrenaline applied iontophoretically, and prostaglandin E_1 antagonises this response⁶. Lithium has also been found to block noradrenaline-induced formation of cyclic AMP in rat cortical slices¹² with relatively low concentrations, and this, together with the data reported here supports the hypothesis that cyclic AMP mediates monoamine response in the rat hippocampus.

Although my data are compatible with the view that Li^+ could block the noradrenaline receptor through an action on cyclic AMP synthesis, earlier alternative assumptions of Li^+ action based on such findings as increased uptake of noradrenaline by brain synaptosomes¹³, decrease in the release of noradrenaline and serotonin from brain slices¹⁴, cannot be eliminated. The iontophoretic mode of application, in spite of its many advantages, tests actually the acute effects of Li^+ which might be different from the effects of a chronic Li^+ treatment. Further electrophysiological study of Li^+ actions in a chronically treated preparation are required to clarify these possibilities.

I thank Drs F. E. Bloom and G. R. Siggins for comments on the manuscript.

Suppression of phage nonsense and temperature-sensitive mutants by an *suA* mutant *E. coli*

BECKWITH and Scaife^{1,2} showed that the suppressor allele *suA* of *Escherichia coli* does not suppress nonsense codons in the lactose operon, but does relieve the polarity effect of UAG, UAA and possibly frameshift mutations. It is shown here that *suA E. coli* strongly suppresses phage T4 amber mutations and weakly suppresses phage T4 temperature-sensitive and amber

mutations. Suppression of the inhibitory effect of chloramphenicol on phage T4 growth by *suA* was also shown. In addition, amber mutants of phage T7 were observed to be suppressed by *suA*. These results suggest that *suA* in addition to suppressing polarity in *E. coli* also increases translational ambiguity in T4 and T7-infected cells, especially for the amber codon.

All phage T4 strains used in this study as well as *E. coli* strains CR63 (*su*-1⁺ UAG), *E. coli* B (*su*-) and *E. coli* BB (containing an amber suppressor, as described by Wilson and Kells³) were from the California Institute of Technology stock collection, under the case of W. Wood. *E. coli* CAJ68 (containing a UGA amber suppressor) was provided by D. Mount, University of Arizona. *E. coli suA* XA7007, F⁻, Δ(Lac-Pro), Mal⁻, B₁⁻, Str^r, Δλ and *E. coli su*- Sy106 were a gift from W. Summers, Yale University and were the strains used in all burst size determinations. Sy106 is an isolate of the original strain from which XA7007 was derived and has the same genetic markers. The presence of the identifying markers in *E. coli suA* XA7007 and *su*- Sy106 were confirmed here. A related *su*- strain, *E. coli su*- XA7014, was obtained from J. Beckwith. The phage T7 strains used were originally from the laboratory of W. Studier and were supplied by T. North at the University of Arizona.

The suppression of phage amber mutants (Table 1) was compared by burst size measurement in four *E. coli* strains (CR63, *suA*, *su*- and B). Unadsorbed phage, measured in a chloroform-treated aliquot taken before the end of the eclipse period, were subtracted when they constituted more than 5% of the final phage yield. Clearly *suA* is comparable with CR63 in the efficiency of its suppression of amber mutants whereas *su*- is about as inefficient as B. In general, amber mutants defective in catalytic functions showed greater burst sizes on suppression by *suA* than those defective in stoichiometric functions⁴. When further tested on plates, the efficiency of suppression by *suA* of most of the amber mutants was high enough to allow these mutants to form plaques. When either the *su*- strain obtained from Summers (Sy106) or the *su*- strain obtained from Beckwith (XA7014) was used as an indicator, no plaques were formed.

The suppression of phage temperature-sensitive (*ts*) mutants is compared in the *suA* and *su*- strains at various temperatures (Table 2). The *ts* mutants defective in catalytic functions seem to be significantly suppressed by *suA* at higher temperatures. Although there is some suppression of *ts* mutants defective in

stoichiometric functions by *suA* at higher temperatures, it is less striking.

The suppression of the phage umber mutants by CAJ68, *suA* and *su⁻* is shown in Table 3. *SuA* seems to be a significantly more effective host in supporting growth of umber mutants than *su⁻*, but not nearly as effective as CAJ68, which contains a specific umber suppressor. This low efficiency of suppression by *suA* of umber mutants is similar to the low efficiency of suppression of *ts* mutants reported above and in contrast to the high efficiency found for amber mutants.

* Average of two experiments.

† Average of three experiments.

The burst sizes of phage T7 amber mutants in three *E. coli* strains (BB, *suA* and *su⁻*) are compared in Table 4. *E. coli suA* is comparable with *E. coli* BB (which contains an amber suppressor) in the efficiency of its suppression of T7 amber mutants. In contrast, growth of T7 on *E. coli su⁻* is at least an order of magnitude less efficient. Where *E. coli su⁻* was used as a plating indicator, no plaques were obtained. When *E. coli* BB or *suA* was used as a plating indicator, large distinct plaques were formed. *E. coli suA* thus seems to suppress T7 and T4 amber mutants with about the same efficiency.

In the experiments described in Table 5, chloramphenicol was added 1.5 min after infection. At 11.5 min after infection it was diluted out so that phage growth could proceed. Recovery from the chloramphenicol effect was then measured in terms of burst size after completion of the infectious cycle. As Table 5 shows, burst sizes after chloramphenicol treatment were only 22–27% of normal in *E. coli* CR63, S/6, and *su⁻*. However in *E. coli suA* the burst size after chloramphenicol treatment was 70% of normal.

‡ These apparent burst sizes are probably due to unadsorbed phage.

The results presented here indicate that the *E. coli suA* mutant suppresses amber mutations of phages T4 and T7, *ts* and umber mutations of phage T4, as well as the chloramphenicol-induced inhibition of phage T4 growth. The most plausible explanation

for the suppression of such varied blocks to growth is that the *suA* mutation of *E. coli*, when present in phage T4 and T7-infected cells, increases the level of translational ambiguity. In its ability to suppress various different mutations, the *suA* allele seems similar to ram, the ribosomal ambiguity mutation of *E. coli*⁵. It may be that *suA* is also altered in a translational element. The product of the *suA* gene has been partially purified by Wetekam and Ehling⁶ and has been shown to act at translation even when uncoupled from transcription.

Suppression of amber, *ts* and umber mutants defective in stoichiometric functions was usually inefficient compared with suppression of such mutants defective in catalytic functions (Tables 1, 2 and 3). Catalytically acting proteins may allow normal burst sizes even when present in reduced amounts whereas stoichiometrically acting proteins will not allow normal burst sizes unless present at near wild-type levels⁴. The burst sizes obtained after suppression of amber, umber and *ts* mutations in stoichiometric functions implies that suppression by *suA* usually restores a low level of functional gene product. The few stoichiometric mutants which were suppressed efficiently suggests that the level of suppression is context or gene specific.

Table 4 indicates that *suA* is an effective suppressor of phage T7 amber mutations, when burst size is the criterion of suppression. Summers⁷ using the *suA* strain used here (XA7007) observed that on infection by a phage T7 amber mutant defective in gene 1 (RNA polymerase) mRNA formation continued beyond the amber codon, whereas in *E. coli su⁻* it did not. Furthermore, he noted in the *suA* infection that short polypeptide fragments corresponding to a defective gene 1 product were formed. This indicates that at least some of the time translation is terminated at the amber codon in the *suA* host. However his result does not preclude the possibility that occasionally synthesis is continued beyond the amber codon. As discussed above, under conditions where essential enzymes are produced at a low level, phage yield may nevertheless be normal because of the catalytic nature of enzyme function. Thus Summers' results are compatible with our conclusion that *suA* is an effective suppressor of the amber phenotype of phage T7.

The effect of the *suA* allele on suppression of the amber codon as observed in phage T4 and T7-infected cells was not observed in uninfected *E. coli*^{1,2,8}, although only few bacterial mutants were tested. Hsu and Weiss⁹ and Schedl *et al.*¹⁰ have presented evidence that ribosomes extracted from uninfected cells are more active than ribosomes extracted from T4-infected cells *in vitro* when used in translating mRNA from *E. coli* or MS2. This suggests that T4 proteins alter ribosomal template specificity. Smith and Haselkorn¹¹ showed that proteins either induced or modified by phage T4 become associated with the *E. coli* ribosomes after T4 infection. Similar proteins may be produced by phage T7. It may be that one or more of these proteins alter the ribosomes' susceptibility to the effect of the host *suA* allele. If the *suA* allele acts at the level of the ribosome, which is then the initially determined phenotype of the mutant, suppression of polarity^{1,2} might be due to an increased tendency of *suA* cell ribosomes to continue along the mRNA after encountering a nonsense codon so as to be available at the next initiating codon. The continuation of the ribosomes would also protect the mRNA against the degradative action of RNases.

Morse¹² presented evidence that chloramphenicol induces an

Table 5 Suppression by the *suA* allele of the chloramphenicol-induced inhibition of phage T4D growth, expressed in burst size

Phage infections were carried out at 30° C. To 0.5 ml of bacteria at about 2×10^8 cells ml⁻¹, 0.5 ml of phage were added to give a multiplicity of infection of 13 phage per bacterium. When the infection had proceeded for 1.5 min, 100 µg of chloramphenicol in 0.1 ml was added. At 11.5 min after infection, 0.1 ml of culture was diluted 4×10^{-4} -fold and growth was allowed to occur for 2 h. At this time phage progeny were determined by plating on *E. coli* CR63 and the burst sizes calculated. All figures are the average of three experiments.

artificial polarity effect on distal mRNA in the *E. coli* tryptophan operon, and that this polarity effect is relieved by the *suA* allele. Table 5 indicates that *suA* also suppresses the effects of chloramphenicol on phage growth. Thus there are somewhat parallel effects of *suA* with respect to chloramphenicol in the two systems. Chloramphenicol is thought to block the transfer of the amino acid from aminoacyl tRNA to the growing polypeptide chain¹³. Since chloramphenicol affects a process taking place on the ribosome it is reasonable to suppose that the *suA* reversal of chloramphenicol inhibition could be due to an effect of *suA* on ribosomal function.

Kuwano *et al.*¹⁴ found a greater release of mRNA fragments *in vitro* by a crude extract of *su*⁻ compared with a similar extract of *suA*. This release was thought to be brought about through the action of an endonuclease which they tentatively designated endonuclease A and which was presumed to be present in *su*⁻ cells, but defective in *suA* cells. Although there is no simple way to reconcile this result with the suppression effects I have observed, it could be supposed that endonuclease A binds to ribosomes and affects the accuracy of translation.

In conclusion, the observations reported here suggest that the *suA* allele produces an altered translational element which enhances mistranslation of the genetic code in phage T4 and T7-infected cells. The wild type form of the *suA* translational element may be necessary both for accurate translation and the dislodgement of the ribosome from the mRNA after reading a nonsense codon.

I thank Norreen Ruth Holmes and Drs Harris and Carol Bernstein for helpful criticism of the manuscript. This work was supported by grants from the National Institute of Health and the US National Science Foundation.

Correlations between plasma ACTH concentrations and breathing movements in foetal sheep

BREATHING movements *in utero* are a normal accompaniment of foetal life¹⁻³. Dawes *et al.*³ reported an instance of reduced foetal breathing in a sheep with spontaneously occurring foetal hypoxaemia. Subsequent observations have shown similar reductions associated with foetal hypoglycaemia, infection, and maternally administered hypoxaemia. In addition they are influenced by hypercapnia, temperature

and time of day⁴. In human pregnancy reduced foetal breathing is associated with maternal hypertension and foetal growth retardation⁵. Thus breathing movements have been used as an index of foetal health. The concentration of adrenocorticotrophic hormone (ACTH) in the plasma of foetal sheep increases during hypoxaemia, haemorrhage and catecholamine infusion (refs 6-8 and C. T. J., K. B., J. G. Ratcliffe and J. S. R., unpublished observations) and may therefore reflect foetal condition. At present blood gas values, pH and heart rate are used as indices of foetal health *in utero* in animals and man. But we have observed a wide variation in plasma ACTH concentration and foetal breathing movements in foetal sheep *in utero* in circumstances in which blood gas values, arterial pH and heart rate were in the normal range. The present report describes a close correlation between the amount of foetal breathing and the foetal plasma ACTH concentration.

In 18 sheep of mixed breeds 120-145 d pregnant with catheters previously implanted in the foetal trachea and carotid artery, carotid blood samples were taken from

Fig. 1 Foetal carotid plasma ACTH concentration and incidence of foetal breathing movements. Each point, represents the foetal plasma ACTH concentration either at the beginning or the end of the hour that the incidence of foetal breathing was measured. Observations at both times were made on most animals.

mother and foetus and ACTH and corticosteroid concentrations were measured as previously described^{7,8}. Sampling took place at least 1 week after surgery, between 9000 a.m. and 1030 a.m. The mean foetal carotid arterial pH and P_{O_2} were respectively 7.37 ± 0.07 (s.e.m.) and 22 ± 0.5 mm Hg and the mean foetal heart rate was 157 ± 14 beats min^{-1} . There was a reciprocal correlation between the incidence of foetal breathing movements over an hour and the foetal plasma ACTH concentration at the beginning and end of that period. There was no correlation with foetal blood gas values, pH, plasma corticosteroid concentration or heart rate. The relationship observed between foetal breathing and plasma ACTH concentration was not directly related to gestational age.

In the foetal sheep dissociation of the electrocorticogram

into high and low voltage activity is first seen around 120 d gestation. Foetal breathing movements are only seen in association with the low voltage activity characteristic of rapid eye movement sleep³. Bernhard and coworkers⁹ have suggested in the foetal sheep that the development of the dissociation and hence rapid eye movement sleep probably originates in the corpus callosum and thalamus. It is possible that the activity in these structures during rapid eye movement sleep may have some connection with that which influences the hypothalamic control of ACTH secretion.

The inverse correlation between foetal breathing movements and ACTH concentrations is not surprising since both are influenced, in opposite directions, by hypoglycaemia, hypoxia, haemorrhage and infection (refs 4, 5, 8, 10–12; K. B., G. S. Dawes and J. S. R., unpublished observations). But none of these factors was directly responsible for the variation in breathing movements or plasma ACTH concentration in the present series of observations. The wide variation in ACTH concentration observed in the foetus and its sensitivity to various types of stimulation such as hypoxaemia or catecholamine infusion^{6,7,10} is surprising in view of the relative insensitivity to ACTH of the foetal adrenal output of glucocorticoids^{6,13}. This explains the absence of a correlation between breathing movements and plasma corticosteroid concentration in foetal sheep.

These observations indicate that the measurement of foetal blood gas values, arterial pH and heart rate alone do not fully reflect foetal condition. Other factors such as the incidence of foetal breathing movements and plasma hormone concentrations are required for the assessment of the physiological state of the foetus *in utero*.

Redistribution of endogenous gibberellins in geotropically stimulated roots

THE difference in growth rate of the two sides of geotropically reacting plant organs is generally explained by the well documented unequal auxin concentrations in the two halves. The auxin ratio in horizontally placed stems, coleoptiles, and roots usually attains a value of about 2:1 in favour of the lower half.

But, Phillips¹ and Railton and Phillips² have shown that the ratio of gibberellin activity in diffusates from opposite halves of geotropically reacting green *Helianthus* hypocotyls and etiolated *Zea* coleoptiles reaches values of about 9:1 and 4:1, respectively, in favour of the lower (convex) half. These findings raise the question of the possible role of gibberellins in the geotropic reactions of these organs.

In horizontally positioned main roots, auxin accumulating in the lower (concave) half, presumably in supraoptimal concentrations, has been postulated to retard the elongation of that half, thus bringing forth the positive geotropic curvature. The correctness of this view has been questioned for some time^{3,4}, and unspecified inhibitors have been suggested as mediators of the differential rates of elongation^{5–8}. In this situation, and in view of the reports on asymmetrical gibberellin distribution in geotropically stimulated shoots, it would be interesting to determine the distribution of gibberellins in horizontally positioned roots. For this purpose the following experiments were carried out.

Seeds of *Vicia faba*, cultivar Erfordia, were soaked for 4 h in tap water and sown in moist vermiculite in the dark at 25° C. All subsequent operations took place under a green safelight. After 4 d, 500 (or 250) seedlings having roots approximately 15 mm long were selected for root uniformity. Of these, 250 (or 125) were left upright and 250 (or 125) were kept horizontal for 30 min. Using a sharp blade, each root was then split lengthwise into two halves. Four batches of root halves were thus obtained: upper and lower halves of horizontally oriented roots, and left and right halves of upright roots. Each batch was extracted at 2° to 3° C with three changes of 80% methanol over 36 h. The acidic fractions soluble in ethyl acetate were passed through a column of polyvinyl pyrrolidone (PVP), eluted with phosphate buffer (pH = 8.0), and transferred in diethyl ether to small volumes of ethanol. These were loaded on silica gel thin layer chromatography plates, which had been prerun in a 98:2 (v/v) mixture of ethanol and acetic acid⁹ and activated at 105° C for 1 h. The plates were developed with isopropanol, 25% specific gravity 0.91 ammonia and water, 10:1:1 (v/v). The chromatograms were divided into 10 transverse strips each of which was scraped off, eluted with 2 ml distilled water, and bioassayed for gibberellin activity in the *Lactuca* hypocotyl assay¹⁰.

As a check on the accuracy of the splitting of the roots, the dry weights of matching, extracted halves (250 in each group) were compared. They were: upright roots, left halves: 0.54 g, right halves: 0.56 g; horizontal roots, upper halves: 0.42 g; lower halves: 0.43 g.

Our results confirm the few available reports on the occurrence of gibberellins or gibberellin activity in roots^{11–13}. As shown in Fig. 1, more gibberellin activity was found on chromatograms of extracts from the upper than from the lower halves of horizontally oriented roots, whereas the amounts of gibberellin activity detected in left and right halves of upright roots were nearly identical.

By comparison with gibberellic acid (GA₃) standards the gibberellin activities in the upper and lower halves of horizontal roots were found equivalent to 31.0 and 17.5 ng GA₃ per g dry weight of tissue, respectively, in experiment b (Fig. 1). In experiment c, representing a different set of roots, the figures were 35.0 and 9.5 ng, but the growth

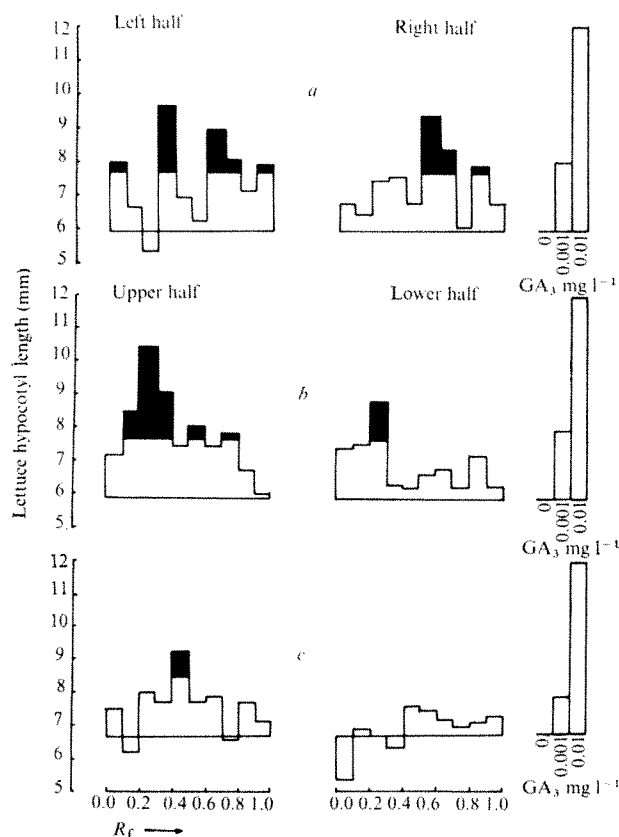

Fig. 1 *Lactuca* hypocotyl bioassays of acid, ethyl acetate-soluble fractions of chromatographed extracts of halved *a*, upright and *b* and *c*, horizontal *Vicia faba* roots. Extract equivalent to 0.2 g dry weight of roots in *a* and *b*, and to 0.1 g dry weight in *c*. A difference of 1.89 mm between any two readings is needed for statistical significance at the 5% level (base of the black parts). Gibberellic acid (GA_3) at 0.001 mg l^{-1} equals $2.6 \times 10^{-9} \text{ M}$.

promotions by the extract of the lower halves were too small to reach statistical significance. (The GA_3 ratio in favour of the upper half was 1.8:1 in experiment *b*; and in experiment *c* the calculated value was 3.7:1). In upright roots (*a*) the GA_3 activities in opposite halves were equivalent to 26 and 24 ng GA_3 per g dry weight.

In further experiments, to be reported in detail elsewhere, zones of the chromatograms running at the same R_f s as GA_3 were eluted with ethanol, methylated¹⁴ and subjected to gas liquid chromatography. The methyl ester of GA_3 was identified at the position (retention time) of methylated, authentic GA_3 . In terms of ng per g dry weight of root tissue, the following quantities of GA_3 were recorded: upper halves: 130, lower halves: 63 (ratio upper: lower = 2.06); right halves: 70, left halves: 74. Qualitatively the distributions were thus similar to those found by the bioassays.

The direction of the concentration gradient of gibberellins in the horizontally positioned *Vicia faba* roots is opposite to that found in shoot tips and coleoptiles^{1,2}. The direction of the gradient is also opposite to that of auxin. Theoretically, gibberellin might thus assist in the positive geotropic reaction by stimulating the elongation of the upper half, provided that gibberellin does stimulate root elongation.

Pilet¹⁵, working with intact seedlings of *Lens culinaris*, found no effect on root elongation by GA_3 at concentrations up to $1 \mu\text{M}$, whereas 10 and $100 \mu\text{M}$ GA_3 retarded growth. There are, however, a number of reports indicating a stimulation by gibberellins of root elongation in some plants: *Pseudotsuga*¹⁶, *Lycopersicon* (excised)^{17,18}, *Triticum*¹⁹, and *Carthamus*¹⁹.

In our own experiments (to be reported in full elsewhere) GA_3 was added to germinating *Vicia faba* seeds when their radicles had just broken the seed coat. The root lengths were measured after 24, 36, and 48 h. GA_3 was found to be stimulatory at concentrations from 0.001 to 10 mg l^{-1} (except at 1.0 mg l^{-1} at 24 h). At all times 100 mg l^{-1} was inhibitory. Seedlings of *Lepidium sativum* were transferred to GA_3 solutions on filter paper when their roots were about 20 mm long. The root lengths were measured after 1, 2, 3, 4 and 5 h. In the first hour, 10 and 100 mg l^{-1} were inhibitory, whereas lower concentrations had no significant effect. At 2 h there was a stimulatory trend at concentrations from 0.1 to 10 mg l^{-1} , whereas 100 mg l^{-1} was inhibitory. At 3, 4 and 5 h, all concentrations from 0.001 to 100 mg l^{-1} were stimulatory, the lowest concentration being the most effective.

Gibberellin may thus have a function in root geotropism, but since the geotropic response in roots involves a retardation of the elongation of the lower part, the action of an inhibitor of root elongation in that part cannot be dismissed. Although such a role has traditionally been assigned to auxin, several authors⁵⁻⁸ leave open the identity of the actual functioning inhibitor. The presence in roots of an inhibitor which is not auxin, but becomes distributed like auxin in horizontal roots, has been demonstrated in this laboratory and its characteristics are being studied.

Batesian mimicry without distastefulness?

MANY distasteful species are conspicuously coloured¹ and this is believed to aid their survival through the formation

of 'avoidance images'² by predators. It has been suggested that 'an efficient escape mechanism' either provided by a jumping response^{3,4}, or a fast escape flight⁵⁻⁷, could be as powerful as distastefulness in influencing a predator's strategy of prey selection, or could in some instances help to increase the relative frequency of an agile mimic of a distasteful but sluggish model⁴. Lindroth⁸ has made observations on several genera of flea-beetles (Alticinae, Chrysomelidae) and has found great external similarities between them and ground beetles of the genus *Lebia* (Carabidae), the larva of which is an ectoparasite of the flea-beetle's pupa. He suggests that the flea-beetle, which can escape suddenly from its exposed position on the food-plant by jumping, acts as a model and *Lebia* as a relatively sluggish mimic. As a parasite, *Lebia* is found in fewer numbers than the host, a situation also expected of some mimics in relation to their models. Neither was found to be distasteful to bird predators⁹. Thompson¹ makes use of Lindroth's⁸ hypothesis in explaining the occurrence of an apparently aposematic form in females of the non-mimetic common meadow spittlebug, *Philaenus spumarius*, which is acceptable to predators but for the possession of an efficient close-quarter escape mechanism. Thompson proposes that this mechanism accounts for aposematic morph *P. spumarius marginella* occurring at a frequency in the population above that maintainable through apostatic selection. In both cases it is proposed that a learning predator comes to associate a particular colour pattern with wasted effort and spurns all forms with a similar appearance.

This report describes a preliminary experiment to simu-

Fig. 1 Percentage of aposematic model/mimic, cryptic model/mimic and non-mimetic seed taken by the experimental birds during the learning period (model) and retention period (mimics). —, Green seed; ---, blue seed; ···, red seed.

late this efficient escape and assess its effectiveness on a predator's selection of prey. *Bathilda ruficauda*, the star finch, was used as the predator and the prey was white millet seed dyed red, blue or green with food colouring (1% acetic acid base). The escape mechanism was simulated by means of a manually-operated hinged feeding platform which could be lowered rapidly to remove the seed from the birds' sight. The platform base was coloured with dots of blue and green dye, the same size as the seeds, and on this the red seeds appeared 'aposematic' and the blue and green seeds 'cryptic' to the human eye and presumably to the birds⁹. In front of the platform was a feeding perch and a light was turned on above to signal the presence of seed.

On each testing day the birds were deprived of food for 1½ to 2 h, transferred to the test cage individually (to prevent observation learning¹⁰) and presented with nine seeds, three of each colour, individually in random order.

The time taken to come to the feeding perch and make a peck at the seed was noted, an upper limit of 2 min being imposed for each seed. After this time the platform was dropped to remove the seed if it had not already been eaten. This operation was repeated three times a day for each bird.

Two groups of four birds were used, one control and one experimental group. The controls were allowed to feed on all seed colours for 3 d. In the experimental group the green represented the 'non-mimetic' on which feeding

Fig. 2 The model-mimic/non-mimetic ratio (M/N Ratio) of mean feeding latency. A measure of the comparative advantage of the model-mimic complex over the non-mimetics. Feeding latency ratio; ■, red/green seed; □, blue/green seed.

was allowed throughout the experiment (days 1-16+23). The blue and red seeds acted as the 'models' during the first half of the experiment, the learning period (days 1-7), by being dropped out of sight as the bird attempted to feed. During the second half of the experiment, the retention period (days 8-16+23) the platform was not dropped for any seed until the end of the 2 min feeding time. The blue and red seeds were then being used as 'mimics'.

The results for the control group show that there was no colour preference in terms of mean feeding latency (Kruskal-Wallis one-way analysis of variance by ranks¹¹. $H=0.54$, $P=0.104$). The experimental group on day 1 also showed no colour preference (Fig. 1). During the learning period, discrimination took place between the non-mimetic (green) seed and the model (blue or red) seeds in terms of latency to feed. The aposematic (red seed) showed the greatest initial advantage over the non-mimetic (green seed), by being avoided before the cryptic model, and more often overall ($\chi^2=38.12$, d.f.=2, $P<0.001$), though the blue model also showed an advantage over the non-mimetic (green seed) ($\chi^2=26.4$, d.f.=2, $P<0.001$) (Fig. 1).

The use of daily mimetic advantage measurements (model or mimic/non-mimetic, feeding latency ratio) shows more clearly the relative advantage of the two model/mimics (Fig. 2); the aposematic model reaching the higher level on day 6. The figure also shows that the relative advantage of red over blue at first increases (up to day 5), then decreases to equality by day 7, the last day of the learning period; from day 11, the fourth day of the retention period, the aposematic mimic shows an advantage over the cryptic mimic. The existence of a mimetic advantage was also apparent when individuals were analysed separately (Table 1).

It was also noted that as the latency before taking a model/mimic seed increased so did the amount of activity unrelated to feeding, including flying around, moving along the perch and preening. A similar type of behaviour was

also exhibited by birds in an experiment on simulated distasteful Batesian mimicry¹² and is probably indicative of a conflict of behavioural tendencies in the animal. This slowing down of attack would give a real mimic more time to escape. Behaviour of this type was never shown towards the non-mimetic (green) seed by the experimental group, nor to any colour of seed by the control group.

The formation of an avoidance image² by the birds was due to the simulated escape mechanism and not to some feature of the apparatus, as the control group fed readily on all seeds from it and the experimental group went for the green seed without hesitation throughout the experiment. Avoidance image formation was therefore through 'frustration learning' which can be as effective as pain learning¹³, the mechanism operative in discriminating distasteful from palatable prey. It would seem then, that 'an efficient escape mechanism' as observed by Lindroth³ could be as powerful as distastefulness in qualifying its possessor as a model for Batesian mimicry. Further observations in the field may show the phenomenon to be less rare than is now supposed.

Table 1 Model-mimic/non-mimetic ratio for each bird during the learning period, retention period and both periods combined

These findings also have implications for the phenomenon of balanced polymorphism in a prey population with aposematic morphs. Birds feed in a frequency dependent manner, the more common the prey the stronger the searching image¹⁴ formed. The selection of apostates (non-mimetic polymorphs) enables a prey species to occur in an area at a greater density than if it were monomorphic. Some of these morphs may appear aposematic and will create a searching image more readily than a cryptic morph. These aposematic forms, if in a species acceptable to a predator, will be found at a very low frequency in the population through apostatic selection mechanisms. *P. spumarius marginella* occurs in an area studied by Thompson⁴ at a level above that of other aposematic morphs, but below that of the cryptic morphs. As all four morphs have the escape mechanism the only difference is that *marginella* is strikingly coloured. In the experiment reported here, learning to avoid the aposematic model was more rapid and this learning was retained longer than for the cryptic model, though they had equally efficient escape mechanisms. In a natural situation the escape mechanisms would presumably be less than 100% effective but, as shown by the experiment, a predator would remember an encounter with the aposematic morph more readily than one with a cryptic morph³. If in a dimorphic species the aposematic form is, say, four times as easy to detect as the cryptic form then the strength of an avoidance or searching image formed would equal that formed by four of the cryptic form. In this simplified hypothetical situation with two morphs, a balanced polymorphic level would be reached when the cryptic morph was four times as common as the aposematic. If the aposematic morph becomes more frequent in the population 'the selective disadvantages of being conspicuous'¹⁴ and predation will increase until the aposematic morph is reduced to the balanced polymorphic level again.

I thank Mr John Lazarus for his reading and criticisms of the manuscript.

Temperature effects on hearing in two species of *Amphisbaenia*

SEVERAL recent studies have documented diverse auditory responses in lizards and turtles as a function of body temperature. Previous work was with iguanid lizards, which are diurnal, and can regulate body temperature by basking; and with the aquatic turtle *Pseudemys*. We have worked with amphisbaenians, which are highly modified burrowing reptiles.

Werner (refs 1 and 2, and personal communication) showed that the ears of six species of iguanid lizards were most sensitive in terms of the electrical potentials of the cochlea at temperatures corresponding either to the 'eccritic' or to the similar 'preferred' temperature. At this optimum temperature the species-specific auditory sensitivity curve is regular and has a characteristic zone of maximum sensitivity². Temperature shifts produce fairly predictable species-specific variations. A temperature drop impairs the sensitivity, especially for the high tones, and makes the function highly irregular, with many sharp variations in frequency. A moderate rise improves the response to high tones while reducing it for low tones. A further elevation is likely to have little effect on high-tone sensitivity, but that to low tones is seriously impaired. In the region of best sensitivity the change often approaches 40 dB. Thus a torpid lizard is likely to have poor perception of sound, even though this may signal a predator or other sort of danger.

A lesser temperature effect was found in the turtle, *Pseudemys scripta elegans*³. For a head temperature range of 14° to 33° C the response to a constant tone of 330 or 630 Hz varied up to 4.3 dB, showing two peaks of sensitivity, respectively at 19° and 29.5° C. According to Patterson *et al.*, temperature has two effects: it acts on the energy source for the generation of potentials and involves either a conductive mechanism or blood pressure.

An earlier study⁴ reported limited observations on a single specimen of the African amphisbaenid *Chirindia langi*. Cochlear potentials differed up to 18 dB in the region around 3,000 Hz between 24.4° and 29.4° C.

Observations on two other species of amphisbaenians now demonstrate strikingly different behaviour. The animals were

four *Blanus cinereus cinereus* (Vandelli) from the vicinity of Jerez de la Frontera, Spain, and three *Diplometopon zarudnyi* Nikolski: one from the vicinity of Dammam, Saudi Arabia, and two from the vicinity of Kuwait. *Blanus cinereus* is probably the most primitive living amphisbaenian, and *Diplometopon zarudnyi* is a highly modified trogonophid.

Specimens were anaesthetised with ethyl carbamate (0.012 ml per g body weight, 20% in physiological saline), often supplemented. The cochlear potentials were recorded with a needle electrode in contact with the perilymph of the saccule while stimulating with various tones over the range of 100 to 10,000 Hz. Temperature was monitored by a thermal probe deep in the cloaca and controlled within 1° C by means of an electric blanket draped over the animal. For details see ref. 4.

Fig. 1 Cochlear potentials of the left ear of *Blanus cinereus* (F868) taken at 25°, 31°, and 34° C in that sequence.

Figure 1 shows sensitivity curves (sound pressure in decibels relative to a pressure of 10^{-5} N m⁻², required at various frequencies to produce a standard potential of 0.1 μ V (that is, the lower the curve, the greater the sensitivity) for a specimen of *Blanus cinereus* at body temperatures of 25°, 31°, and 34° C. The curves differ, especially for the medium low and middle tones, but lack a clear trend as a function of temperature. Figure 2 shows similar observations on specimens of *Diplometopon zarudnyi* at four temperatures between 25° C and 40° C. All curves have the same general form.

A second specimen of *Diplometopon zarudnyi* tested at 37° C and then at 28° C yielded closely similar curves that cross one another several times. There was no obvious temperature effect, despite differences of 5–8 dB at two or three frequencies. The temperature was next set at 43° C, but the animal became hyperactive and a further test run had to be interrupted. After a period of time at a temperature of 35° C, a final series of measurements indicated reduced sensitivity. Possibly the high temperature of 43° C impaired the cochlear response.

These results reveal large differences among reptiles in the effects of temperature upon the response of the ear to sound. *Blanus* and *Diplometopon* maintain a remarkable constancy over a temperature range of as much as 15° C in sharp contrast to the lizards tested by Werner. *Pseudemys* and *Chirindia* evidently are intermediate.

It is as yet impossible to identify the process or processes involved in the observed temperature effects. Werner's observations seem definitely to exclude the sound conductive pathways, and point to the cochlear processes, and probably the hair cells themselves. The temperature effect may depend upon the magnitude of the polarisation potential set up at the surface membrane of the hair cell, and reflects the metabolic processes and membrane permeabilities by which this polarisation is established. Such possibilities should be tested and interspecies differences more broadly assayed. Do the responses reflect such environmental parameters as the range across

Fig. 2 Cochlear potentials of the left ear of *Diplometopon zarudnyi* (F869) taken at temperatures of 25°, 31°, 36°, and 40° C as indicated.

which a species normally thermoregulates? Can these amphisbaenians control the temperature of the otic capsule independent of general body temperature?

The sensitivity curves represented above show considerable variability tentatively attributed to the activity of middle ear muscles connecting to the terminal disk of the columella and probably affecting sound transmission to the inner ear⁵. Their activity may explain instability in the meter readings during presentation of a steady tone.

Efforts in one experiment to reduce this instability by the use of curare (*d*-tubocurarine) yielded uncertain results, perhaps because we were overcautious in the dosage used. Further experiments are needed on a more readily available amphisbaenian.

We thank M. Moya, J. Mandaville, A. d'A. Bellairs, and S. Howe who made these animals available for study. The work of C. G. is supported by a grant from the National Science Foundation, and that of E. G. W. by a grant from the National Institutes of Health.

Green cones of the piñon pine stimulate late summer breeding in the piñon jay

REPRODUCTION in birds is influenced by a variety of environmental factors, usually classified as ultimate or proximate¹. Ultimate factors determine efficiency of breeding, for example food supply for the young² both before and after they become independent of their parents. Proximate factors, on the other hand, are the timers or predictors which initiate breeding at the appropriate time. Photoperiod is the most reliable and

Fig. 1 Testicular response of three adult piñon jays provided freely with green cones of the piñon pine. Testes were regressing in ten experimental birds and ten controls through June and July. On August 1 the dried piñon seeds provided to the experimental jays were replaced with green unripened cones of the piñon pine. In three individuals shown here (A, B, C), testis regression was then reversed and the gonads enlarged. The unhatched bar represents maximum testis volume of the ten control piñon jays.

common proximate factor in those temperate zone species which breed exclusively in spring when daylength is increasing². Other proximate factors, such as rainfall, provide predictive information in many regions of the world, in that increased food availability follows the rains³.

Although most birds in temperate zones breed in spring and early summer, a few breed at other times of the year as well, in autumn or even winter⁴. In most such cases food abundance has been thought to be a primary stimulator of reproductive activity; however, with a single exception⁵, experimental support is lacking³. I report here field and experimental evidence that late summer–autumnal reproductive activity in piñon jays (*Gymnorhinus cyanocephalus*) of the south-western United States is triggered by the presence of large quantities of green cones of the piñon pine (*Pinus edulis*), which mature in late summer. Piñon pines in a given area produce cones and seeds largely in synchrony at irregular and infrequent intervals.

Piñon jays, like most other temperate zone bird species, are responsive to increasing photoperiod in spring (my unpublished work), and typically breed from late February or

early March to June⁶⁻⁸. In south-western New Mexico, however, near the south-eastern edge of this bird's range, climatic factors, and thus food availability, are unpredictable in spring and early summer and, as a result, breeding pattern and timing of the annual moult vary from year to year in a single population^{6,9}. It is here that late summer breeding sometimes occurs^{6,10}, and it seems to be related either to abundance of green cones of the piñon pine or to seeds contained within the cones (Table 1).

To test the roles of mature piñon seeds and the resinous green cones which contain maturing seeds, I spatially isolated two groups of ten adult male piñon jays in outdoor aviaries for 1 yr, beginning on September 1, 1971. One group received a nutritionally adequate diet, but with no piñon seeds or cones, whereas the other received the same diet, plus mature piñon seeds. The birds were laparotomised and their testes measured at monthly intervals.

No gonadal growth occurred in either group until the vernal increase in photoperiod, and through most of the year gonadal development was similar in both groups. By summer 1972 testes of all birds were regressing. On August 1, 1972, the ten jays receiving piñon seeds were instead given free access to intact, fresh, green piñon cones for a month. Regression of the testes was reversed in three birds (Fig. 1); that is, whereas dried piñon seeds did not prevent or delay regression of the testes, availability of green cones reversed gonadal regression and stimulated testis growth in some of the experimental birds. Gonads of the ten controls remained small (4.1–12.9 mm³, mean = 7.8 mm³), as did those of the seven experimental birds (1.4–12.5 mm³, mean = 7.8 mm³).

It is not surprising that most jays did not respond. The captive jays had neither mates nor suitable nesting sites, both of which are important in the attainment of reproductive competence in many birds¹¹. Further, in 1969, when autumnal breeding occurred, only about a third of the flock of about 300 jays actually bred⁶. As indirectly indicated in Table 1, natural selection favours no autumnal breeding in most years. Thus one could expect polymorphism in gonadal response to environmental stimuli in this population of piñon jays.

These data suggest that green piñon cones *per se* provide long term predictive information to the piñon jays; that is, the cones serve as proximate factors. In late summer, as a result of seasonal rains, other foods such as insects, are plentiful in every year, and it seems that piñon jays could easily provide for nestlings at this time. (It should be noted that piñon seeds form a very minor portion of the diet of nestlings^{6,12}.) Immature piñon jays become independent at about 8 weeks of age⁷. In birds hatched during autumn this occurs shortly before the onset of cold, temperate weather. Great quantities of cones in August provide the proximate cue that adequate food, in the form of piñon seeds, will be available to the callow young during the stressful winter season.

I thank Sandra L. Husar for assistance. The Research Allocations Committee of The University of New Mexico provided financial support for much of this study.

Pentamerism and the ancestral echinoderm

ONE of the difficulties in an account of the origin of the echinoderms is their five-fold radial symmetry. Nichols¹ has proposed a hypothetical ancestral echinoderm derived from a lophophorate ancestor. Sipunculoids have a recurved gut and a hydraulically operated tentacular system using a special compartment of the coelom. These resemblances to echinoderms suggest that a sipunculoid-like animal might have given rise to an ancestor of the echinoderms by developing a calcite skeleton for protection. This ancestor is illustrated in cross section in Fig. 1, but Nichols was unable to say why it should be pentamerous. On analysis of the requirements of such an animal, however, it has been possible to produce a 'paradigm' (in Rudwick's sense²) which demands five rays.

Fig. 1 Nichols' hypothetical ancestral echinoderm, in cross section.

Nichols' reconstruction, like many primitive echinoderms, has mouth, hydromore and anus in a straight line. Such an animal must live with the anus on the downstream side, to carry waste products away from mouth and hydromore (Fig. 2a). (In tidal waters, one current would probably be dominant, either because it would be stronger, or because it would carry food.) The hydromore fits best downstream of the mouth, where the current over it is filtered by the food-gathering apparatus. The lophophore of such an animal must serve three functions: first, to catch food settling vertically out of suspension; second, to catch food food carried along horizontally by the current; and third, to detect the approach of danger.

The third function needs a ray extended directly upstream (Fig. 2a), which would also serve the first two functions to some extent, but more rays are needed for food gathering. These must be bilaterally symmetrical about the axis established in Fig. 2a, or the animal would be twisted by the current. An additional ray extending downstream would only be possible if it did not lie on the surface of the theca, as in an edrioasteroid, but was extended over hydromore and anus as an arm. This would be undesirable as the arm would hinder the current in carrying away waste products, and might create eddies carrying these products into hydromore or food groove. There must, therefore, be an odd number of rays; one extended upstream and pairs on either side of the axis: one pair of rays at right angles to the axis (Fig. 2b) catches food carried horizontally by the current, but makes no provision for catching food settling vertically or for detection of danger on the downstream side of the animal. These functions would be better served if all the rays met at equal angles (Fig. 2c). If each lateral ray is of length r , it would then sample a section of the current width $w = r \sin 60^\circ = 0.866r$. Each ray would also extend 'early warning' downstream from the centre by a length

Fig. 2 Possible paradigms for an ancestral echinoderm. ⊕, Mouth; ○, hydromore; ⊙, anus; r , length of ray; w , current width searched; l , extension of 'early warning' facility downstream. Short downward arrows in b, c, d represent current direction.

$l = r \cos 60^\circ = 0.500r$. But this is a vulnerable side, predators may be attracted upstream to the animal by secretions carried by the current.

If another pair of arms is added, the requirements of the paradigm can be filled more satisfactorily. The animal of Fig. 2d has five arms of equal length and at equal angles to their neighbours. It is symmetrical to the current with one ray upstream and the anus downstream; each of the anterior lateral rays samples a width of current of width $w = r \sin 72^\circ = 0.951r$ (and it can be shown that this advantage of 5 rays over 3 persists even if the current veers considerably); each of the posterior lateral rays extends warning backwards by a distance $l = r \cos 36^\circ = 0.86r$, while the anterior lateral rays guard the flanks; and finally, five equally spaced rays provide a better net to catch food settling vertically. The addition of a third pair of rays does not produce corresponding advantages.

Five rays like this might be evolved by the branching of the lateral rays of a triad³, or by repeated branching of the

single ambulacrum of an animal like *Helicoplacus*. However, Hyman's summary⁴ of sipunculoids as having "less than 10 to numerous" tentacles suggests that it might fit Nichols' theory better to postulate a reduction of rays to the acceptable minimum of five so that the animal expends the minimum of metabolic energy in calcifying them. This reduction would mean further loss of food-gathering power to a lophophore already restricted in flexibility by calcification, which could be overcome by the provision of lateral branches to the rays as outgrowths of the coelomic canal. Nichols deduced such branches, but from analogies with recent crinoids, he considered the branches would be respiratory. Selection might have favoured their development to meet the needs of both feeding and respiration. Whatever the exact details, the hypothetical ancestral echinoderm has now been equipped with pentamerous symmetry and can give rise to a variety of primitive echinoderms.

I thank Professor D. Nichols for reading a draft of this paper.

Fertilisation of sheep ova following their transfer to goats

AN interesting feature which has emerged from attempts to hybridise domestic sheep (*Ovis aries*) and goats (*Capra hircus*) is the marked difference in conception rate according to the direction in which the cross is made. In goats inseminated with sheep semen the conception rate is similar to that in goats mated naturally with male goats; whereas in sheep inseminated with goat semen fertilisation is an infrequent occurrence¹⁻³. The low fertilisation rate in sheep inseminated with goat semen has been confirmed by Hancock⁴ who found that only 5 of 93 (5.4%) sheep eggs were fertilised by goat spermatozoa.

Here I report an experiment undertaken with a view to isolating the factors which may be involved in the infertility of the sheep and goat cross, the approach being to circumvent any incompatibility between spermatozoa and environment by transferring sheep oocytes to the Fallopian tubes of goats which had been mated with fertile male goats. Results showed that most of the sheep eggs subsequently recovered had been fertilised and were undergoing cleavage, indicating that the sheep ovum presents no intrinsic barrier to the entry of the goat spermatozoon.

Eleven Border Leicester × Welsh Mountain ewes were treated with progestagen-impregnated intravaginal sponges (Veramix Plus; Upjohn Ltd) for 13 d, and were each given 1,500 i.u. pregnant mares' serum gonadotrophin (Folligon; Intervet Laboratories Ltd) by subcutaneous injection at the time of sponge removal. The ewes were then tested with a vasectomised ram twice daily for signs of oestrous activity, and were given either 6,000 µg luteinising hormone releasing factor (Roche Products Ltd) or 500 i.u. human chorionic gonadotrophin (Chorulon; Intervet Laboratories Ltd) by intramuscular injection,

18 h after the onset of oestrus. The animals were subjected to laparotomy approximately 24 h later. Six of the ewes were used as egg donors, the technique for recovery of eggs being that described by Hancock and Hovell⁵. The oocytes were transferred in a small volume of Hank's fluid into the ovarian end of the Fallopian tubes of four crossbred goats (G1, G2, G3 and G4) which had been mated with fertile male goats 30-60 min earlier. The remaining five ewes were inseminated with goat semen; the semen was collected with the use of an artificial vagina, and an equivalent of 2.15×10^9 (range 0.9-4.96) spermatozoa was deposited directly into each uterine horn. Goats G1, G3 and G4 and the inseminated sheep were subjected to laparotomy for egg recovery 3 d after the first operation; goat G2 was subjected to laparotomy 2 d after the first operation. A record was made of the number of corpora lutea in the ovaries of the goats at the time of the second operation.

Table 1 The numbers of sheep oocytes transferred to the left (L) and right (R) Fallopian tubes of mated goats, and the numbers of fertilised and unfertilised ova recovered

Goat	Sheep oocytes transferred		Corpora lutea		Ova recovered	
	L	R	L	R	L	R
G1	3	4	1	0	2 (6-8 cell) 1 (1 cell)	1 (5 cell)
G2	0	1	1	0	—	1 (2 cell)
G3	0	4	0	0	—	zona pellucida with spermatozoa
G4	3	2	0	1	2 (6-8 cell) 1 (1 cell)	1 (1 cell)

A total of six cleaved and three uncleaved ova were recovered from three of the goats (G1, G2 and G4). Assuming that, from the number of corpora lutea, one of the cleaved ova from goat G1 and one of the uncleaved ova from goat G4 were 'native' ova (see Table 1), the results indicate that seven of the transferred ova were recovered at the second operation. Five of the seven ova (71.4%) were cleaved. No ova were recovered from goat G4, but an empty zona pellucida showing the presence of embedded spermatozoa was found.

A total of ten ova were recovered from the five sheep in which goat semen had been placed directly into the uterine horns. None of the ova were fertilised, and there were no spermatozoa attached to, or embedded within, the zonae pellucidae.

Although the number of animals used in the experiment was very small, the fertilisation of transferred sheep oocytes in three goats and the presence of spermatozoa in the zona pellucida recovered from the fourth goat, indicate that there is no innate incompatibility between sheep ova and goat spermatozoa. These findings would seem to suggest that the low fertilisation rate in sheep inseminated with goat semen is due to factors affecting the survival, transport or capacitation of the goat spermatozoa in the ewe.

This work was supported by a grant to Professor J. L. Hancock from the Agricultural Research Council. I wish to thank Mr J. Dearden for technical assistance and for care of the experimental animals.

Swamp cancer

HYPHOMYCOSIS DESTRUENS EQUI, also called swamp cancer or bursattee, is a granulomatous disease commonly of the lower leg of the horse and is a well known condition in the tropics and subtropics¹. The associated fungus, 'Hyphomyces destruens', has neither been legitimately described nor satisfactorily placed in any group of fungi except broadly in the Phycomycetes, on the grounds of the morphology of the hyphae in tissue and culture.

Following recent work in Australia by Johnston and Hutchins², a request was made to these authors for isolates of the fungus from the New South Wales cases, but none had survived more than a few months in culture. This fate has also occurred to the isolates of Bridges and Emmons (H. Hasenclever, personal communication). In September 1973 isolates were obtained from four cases of swamp cancer in horses in the Central District of Papua New Guinea, which closely agreed with the limited description available of 'H. destruens'.

Because of suggestions by Bridges and Emmons³ and by Amemiya and Nishiyama⁴ and its general resemblance to

Fig. 1 *a*, Rotating vesicle of sporangial contents undergoing cleavage into zoospores immediately after emission ($\times 270$); *b*, zoospores encysted at sporangium apex ($\times 270$); *c*, sporangium aperture stained with Parker blue-black Quink ($\times 405$).

Mortierella spp., a number of methods developed to encourage these fungi to produce sporangia were tried out on the cultures, for example, hay and silage agars, but without success. A further attempt was made by placing portions of colonies from a Sabouraud glucose agar plate in sterile water in a Petri dish, to which a small piece of sterilised rotten maize silage had been added. After incubation for 2 d at 25° C biflagellate zoospores 9–10 μ m diameter were noticed arising from the cleavage of protoplasmic masses emitted from undifferentiated filamentous sporangia (Fig. 1).

This behaviour shows that 'H. destruens' is a Phycomycete belonging to the Pythiaceae in the Peronosporales and that it could be included in the genus *Pythium* Pringsheim⁵. Further work is in progress to establish whether it is a recognised or a new species, but the existence of a *Pythium* sp. pathogenic to mammals has not previously been suspected.

Proceedings of the Special FEBS Meeting,
Dublin 1973

INDUSTRIAL ASPECTS OF BIOCHEMISTRY

(FEBS Proceedings Vol. 30, Parts I and II)

edited by B. SPENCER, Dublin

1974. 988 pages. US\$61.50/Dfl. 160.00
ISBN 0-7204-4330-X

These two volumes reflect the increasing importance of industrial and biochemical research and highlight aspects of the science which have previously been neglected.

The first volume contains those papers which deal primarily with protein biochemistry. In addition, a number of papers illustrate the growing importance of biosynthetic techniques and several recent advances in bio-deterioration. The second volume is mainly concerned with the biochemistry of drugs, their mode of action and general metabolism, although there are also some sections on special aspects of carbohydrate and lipid research. Finally, a short section of analytical techniques is included, emphasising the application of certain major concepts in the industrial environment.

As these proceedings represent such a broad range of topics, biochemical laboratories everywhere should find information which is essential to their research.

CONTENTS:

Part 1: Production of Enzymes. Isolation and Purification of Enzymes. Applications of Enzymes in Industry and Medicine. Brewing. Other Fermentations. New Protein Sources. Disposal of Industrial Effluents. Bio-deterioration. Bio-degradation.

Part II: Mode of Action of Antibiotics. Mode of Action of Other Drugs. Drug Metabolism and Activity. Carbohydrates. Lipids. Analytical Techniques.

THE PARADOXICAL NATURE OF REALITY

GEORGE MELHUISE

This book represents a revolution in philosophical thinking. It demonstrates that traditional methods of understanding have failed to define primordial flux. An entirely novel investigation into the nature of change indicates that change is possible only in consequence of definitive paradox and actual indeterminacy. Whenever we define things particularly, we use the principle of identity and bring into play the tautological system of logic, wherein everything is what it is. However, the author shows that the innate change of the experiential moment demands that we disclose the non-tautological system of logic. A paradoxically energetic state is used as the basis for the non-tautological foundations and here a thing is not only what it is. A new philosophical cosmology is put forward. It is shown that it is an error of orthodox doctrine to claim that the universe is only something in particular. It is argued that in order to define reality adequately, we must turn away from dogmatic ideas to a discipline wherein the representation of the finite world as a selectivity implies actuality, only in consequence of the representation of the infinite world as a non-selectivity. We are familiar with the notion of a selective universe, but *The Paradoxical Nature of Reality* outlines, perhaps for the first time, the notion of the non-selective universe. £2.90.

Molecular Biology comes of age

This special *Nature* Supplement has been reprinted as a separate publication. First published in the issue of 26th April 1974, '*Molecular Biology Comes of Age*' looks back on the circumstances surrounding the original appearance in *Nature* of Watson and Crick's revolutionary paper on the double helix structure of DNA in 1953. It discusses the development in Molecular Biology up to the present day as well as prospects for the future. Among the distinguished contributors are Crick, Pauling and Chargaff.

'*Molecular Biology Comes of Age*' takes a fascinating and critical look at a very controversial area of study and will therefore be of special interest to teachers and students as invaluable background material.

Reprints of '*Molecular Biology Comes of Age*' are now available in multiples of five copies at £1.10 surface mail, or £2.00 airmail (10 copies £2.20 or £4.00 and pro rata). Please order copies by completing the order form below and returning it with the appropriate fee.

Circulation Department, Macmillan Journals Limited, Brunel Road, Basingstoke, Hampshire RG21 2XS.

Please send me copies of '*Molecular Biology Comes of Age*', by surface mail/airmail (delete whichever is not applicable).

Butterworths Scientific Fellowship for Authors 1975

Applications are invited for the 1975 Butterworths Scientific Fellowship, founded in 1971 to commemorate 25 years of scientific publishing.

Fellowships during the last three years have been awarded as follows:

1972, Dr. R. D. Cannon, University of East Anglia, for a book on electron-transfer reactions; 1973, Miss M. L. Shackley, University of Southampton, for a work on the analysis of archaeological sediments; 1974, Dr. J. R. Flenley, University of Hull, who is writing on the history of the tropical rain forest. These subjects give an indication of the wide-ranging coverage of the proposals submitted.

- The Fellowship will be awarded for a work of scholarship in the physical or biological sciences, or mathematics.
- The Fellow will be a member of the staff of a British University or Institution of similar standing.
- During the tenure of the Fellowship the Publishers will pay agreed advances against royalties to make good any loss of income occasioned by leave of absence, relief from teaching duties or similar leave required by the Fellow.
- The Fellow must present the manuscript to the Publishers within three months of the end of the Fellowship.
- The Fellowship will be tenable for a period of 3 to 12 months and may be taken up on or before 1 November 1975.
- On acceptance of the manuscript the Fellow will receive an award of £1000 which will be in addition to royalties.
- Applications, supported by a Head of Department or Laboratory Director, must be received by 1 November 1974.

The Fellow will be chosen by the Butterworths Scientific Advisory Board:

Sir Harold Thompson, CBE, FRS Department of Physical Chemistry, Oxford

Professor J. Baddiley, FRS Department of Organic Chemistry, Newcastle upon Tyne

J. A. Charles Department of Metallurgy, Cambridge

Professor F. C. Frank, OBE, FRS H. H. Wills Physics Laboratory, Bristol

Professor J. L. Harley, FRS Department of Forestry, Commonwealth Forestry Institute

Professor J. F. C. Kingman, FRS Mathematics Institute, Oxford

Applicants should write for more information and entry forms to:

The Director of Scientific Publishing
Butterworth & Co. (Publishers) Ltd., 88 Kingsway, London WC2B 6AB

book reviews

Pastures new

Introduction to Ecology. By Paul Colinvaux. Pp ix+621. (Wiley: New York and London, 1973.) £5.80.

Textbook of Theoretical Botany. Vol. 4. By R. C. McLean and W. R. Ivimey-Cook. Pp. viii+3317-3912. (Longman: London, October 1973.) £12.00

Introduction to Plant Ecology: A Guide for Beginners in the Study of Plant Communities. By A. J. Willis. Pp. 237. (Allen and Unwin: London, November 1973.) £5.25 boards; £2.95 paper.

THE publication of E. P. Odum's *Fundamentals of Ecology* (Saunders, Philadelphia, 1959) heralded a new era in the teaching of ecology at university undergraduate level. In particular it was Odum's emphasis upon the ecosystem as the basic unit of ecology which permitted the novel but long-awaited integration of plant and animal studies within a single cover. At last due emphasis was given to the principles governing the flow of energy, the cycling of elements and the dynamics of populations of organisms within the physical constraints imposed by the climatic and edaphic environment. As a result, this book did more than any previous text to influence the development of ecological teaching in universities throughout the world. Traditional plant and animal ecologists have been inspired not only to unite in their research efforts but also in their attempts to convey to their students an understanding of the functional mechanisms at work in natural communities of plants and animals.

The positive feedback system thus created has inevitably resulted in a logarithmic increase in the information accretion rate within the newly unified discipline of ecology. As a result, principles require modification, techniques require revision and new and better examples of many fundamental concepts emerge, all of which serve to make any text less and less useful as a teaching tool with the passage of time. Consumer demand must eventually result in the revision or replacement of traditional textbooks. Odum's text has undergone periodic revision, most recently in 1971, but for several years there has been a need for a fresh look at ecology in its totality by a new author uncommitted to the highly evolved, but often rigid, framework of a previously

published text. Two such texts have recently migrated across the Atlantic to its more conservative right-hand seaboard. One of these, Paul Colinvaux's *Introduction to Ecology*, is to be reviewed here; the other, Robert Ricklefs's *Ecology* (Nelson, London, 1973) was reviewed in these columns last year (245, 342; 1973).

Colinvaux's book is thoroughly refreshing in approach, content and style. The arrangement of material is systematic and sensible. Beginning with plant and animal geography, the author places an unusual, but highly desirable emphasis upon the time factor in the development of the formation (=biome) both on the successional time scale and over longer periods involving climatic change. Colinvaux's informal, even anecdotal, style makes this section particularly easy and exciting to read—his selection of material is so skilled that the founders of biogeography emerge as human beings rather than the stuffy Victorian protagonists pictured in so many texts.

The second part of the book deals with the ecosystem as a unit and, inevitably, it leans heavily upon Odum. But once again the author's highly selective and analytical approach leads to simplicity, consistency and flow in his style. For example, in the opening section of part 2 he reduces the major contributions of Elton, Lindeman and Hutchinson to the development of ecosystem concept to a mere paragraph. The paragraph nevertheless remains readable, full of infectious enthusiasm, yet pregnant with information and meaning. This paragraph forms the basis for his further development of the themes of production, energy transfer and nutrient cycling.

Part 3 of the book deals with competition and the relationship of the individual to the population. Inevitably, this section contains an abundance of animal data, mainly because so few botanists have regarded plants in these terms. Colinvaux's approach is made uniform by the way in which he relates all of the work he reviews to the processes of natural selection and evolution. In the final part of the book he continues the evolutionary theme by asking some of those enigmatic questions which make modern ecology so fascinating; why are some species of organism common whilst others are rare, what controls diversity in ecosystems and how is diversity

related to stability of ecosystems?

It is easy to criticise this book on many aspects of content, particularly the lack of detail in some sections. For example, the descriptive analysis of plant communities (a subject which has riveted the attention of British and Commonwealth plant ecologists for decades, often to the exclusion of all other considerations) is treated very briefly when compared with that of, say, Kershaw's *Quantitative and Dynamic Plant Ecology* (Arnold, London, 1973). Genetic aspects of natural selection and evolution rate receive a less rigorous treatment than in Ricklefs's *Ecology*. But in my opinion, any such defects are greatly outweighed by the sheer readability of Colinvaux's text as well as the effective way in which it stimulates the most fascinating ecological questions in the reader's mind. Any teacher who needs a general ecological textbook to introduce this vast subject to undergraduates need look no further than this book.

McLean and Ivimey-Cook's fourth volume in their *Textbook of Theoretical Botany* is, as its name implies, a massive collection of information relevant to certain aspects of plant ecology and plant geography. One may be forgiven for questioning the relevance of such an encyclopaedic textbook in these days. No longer can the plant sciences be adequately covered in one text, even if it runs to five expensive volumes as this one is intended to do. Indeed, I would even question the need for a textbook embracing plant ecology at a time when ecological synthesis is proving so much more valuable than analysis in the construction of a conceptually based and predictive science of ecology. Even the short preface to this volume conveys to me an air of incipient defeatism: "Many people who meet this unfamiliar word (ecology) for the first time are moved to ask, 'what is ecology?' and 'what does it do?' The present sketch may be useful in answering such questions so far as plant life is concerned."

How, one may ask, can such questions be answered by reference only to plant life? They cannot, and this fact becomes increasingly clear as one proceeds through this book. For example, many conceptual terms are treated inadequately, simply because they depend largely upon animal studies for their existence. The term 'niche' cannot be explained solely with

reference to plants; the semi-quote from Odum that in is the plants' profession is meaningless. Colinviaux asked a much more searching question when dealing with this topic; why are there so many species of grass in a meadow when they are all doing the same job? McLean and Ivimey-Cook not only fail to answer such a question, they do not ask it. Again, how sad it is that seven pages of this concept section are devoted to 'physiognomy' and only one to 'ecosystem'. That single page contains many misconceptions and errors, for example, the confusion of the terms 'population' and 'community', and the idea that an ecosystem must be stable or it will "disintegrate and disappear". Primary production is mentioned here, though not defined, but one has to hunt within the 'edaphic environment' section in order to find two more pages devoted to this topic in the 800-page book.

The coverage of the volume is patchy. Production ecology is almost non-existent, but soils and related environmental factors are dealt with very extensively. Even here, however, there is a tendency to depend upon older literature for much material with resultant inaccuracy; for example, their treatment of organic soils and peats is antiquated and misleading.

It is a little surprising to find three habitats selected for more detailed treatment in a book of this kind. These are freshwater habitats, marine habitats and sea beaches all of which are covered by specialised texts. The use of the term 'sea beaches' is also misleading. Instead of a discussion of the maritime beach habitat one finds a brief account of intertidal benthic algae and their zonation. Here again terms are used loosely; 'emergence' and 'exposure' are both used where 'emersion' would be preferable. The effects of exposure (to wave action) are not dealt with at all, despite their profound influence upon intertidal ecology.

The second (and smaller) part of the volume is concerned with plant geography. This subject is dealt with in a far more satisfactory way than is plant ecology. The approach is generally historical and due emphasis is placed upon tectonic and glacial changes in Tertiary and Quaternary times in influencing the present pattern of plant distributions. There is a very useful section which discusses Adams's criteria for the recognition of centres of origin and distribution of plant genera. This would have been even more useful if it could have been married with some ecological principles. The separation of plant ecology from plant geography, like that of plant and animal ecology, is an historical accident the effects of which

have benefited neither discipline. Our efforts should surely be directed towards healing these breaches rather than preserving them.

One final criticism of McLean and Ivimey-Cook's book is the absence of a bibliography with each volume. Presumably one is expected to buy the fifth volume to benefit from the citations of specific publications in the fourth volume.

The third book under review is the revision by Willis of A. G. Tansley's *Introduction to Plant Ecology*. Having stated my basic reservations about books devoted to general plant ecology and to the revision and up-dating of classic textbooks, I need not labour them further. This revision is a thorough one and has involved the introduction of a large proportion of new material since the final 1954 edition of Tansley's book. At the same time the basic Tansleyan influence remains dominant in concepts and approach.

There are certain areas, however, in which it is impossible to do justice to modern concepts and still to retain the Tansley tradition. For example, the chapter on vegetational succession remains true to Tansley only by omitting the contributions of Deevey, Livingstone, Hutchinson and Odum. A large proportion of the book is given over to the description of vegetation, yet Tansley's ideas on this subject, although a milestone in the history of plant ecology, are now to be regarded in the way a modern radioastronomer would look upon Galileo's telescope. Similarly, a modern ecologist would not look to Tansley if seeking a means of describing vegetation. Can we not allow these classic texts to rest in respected peace upon our shelves and, inspired by their truths but liberated from the straight-jacket of their historical context, set about their replacement with yet greater works? I am sure that Willis and many other revisors would have been more gainfully employed in such a task.

A comparison of the three books under review here sadly reflects the development of ecology on the two sides of the Atlantic. The New World has set about the task of integrating the science of ecology while the Old World remains hide-bound by its much treasured tradition.

PETER D. MOORE

Generations of insects

Insect Population Ecology: an Analytical Approach. By G. C. Varley, G. R. Gradwell and M. P. Hassell. Pp. x+212. (Blackwell Scientific: Oxford and London, 1973.) £2.75.

THIS is an excellent book about insect population dynamics, with emphases on

the construction and evaluation of life tables, on quantitative description of the effects of parasitoids, predators and competitors, and on application of these techniques in the field of biological control. It will be valuable to students and research workers, especially to those working on insects with discrete generations, since this is a basic assumption of most of the models developed here.

It is not a complete text of population ecology, partly because many important ideas have emerged only in the study of vertebrates, and partly because the scope of the book is less wide than the title implies. Other facets of population ecology such as dispersal, insect-plant relationships, effects of environmental heterogeneity and evolutionary aspects are not to be found here. But these omissions are not shortcomings, since this comprehensible treatment of population dynamics is particularly valuable now when the subject is no longer controversial. The disputes of fifteen to twenty years ago were founded partly on difficulties in definition of terms, partly on misunderstandings of cause and effect, and partly on the tendency of researchers to generalise from their own results. Subsequently, in the early sixties, most writers were particularly careful to avoid these pitfalls, but this salutary effect seems to be wearing off. This book should help to reverse the trend once more.

Not all the deductions from population models are strictly accurate. A case in point concerns the authors' own work on the winter moth and its parasites. A high and variable proportion of winter moth larvae dies each year when eggs laid on oak twigs hatch before the buds burst, causing starvation of the larvae. P. P. Feeny whose work is not referred to here, has given evidence (*Ecology*, **51**, 565-581; 1970) that the selection pressure responsible for this very early egg hatch stems from the accumulation of toxic chemicals in the oak leaves later in the season, such that larvae which hatched late would be unable to complete their development. If this is correct, then the interpretation given in the book—that the mortality is caused by "the wide scatter of bud opening times [which] prevents the time of hatch of winter moth eggs from being selected for very precisely"—is only half the story, and the assumption (page 133) that this mortality would be reduced if the buds opened synchronously on all the trees is incorrect. The same selection pressure for early hatching would still be present, and the resulting mortality would simply be more evenly distributed in space. The further assumption that this hypothetical situation would destabilise winter moth populations

seems equally unjustified, since, while the stabilising effect of parasites' responses to patchiness in host density would be removed, the major cause of instability—differences from year to year in the relative timing of egg hatch and bud burst—would, in the authors' interpretation, also be reduced.

M. C. SINGER

Obedient unto death

Obedience to Authority: An Experimental View. By Stanley Milgram. Pp. xvi+224. (Tavistock: London; May 1974.) £2.50.

"I WAS just obeying orders". From My Lai to Auschwitz and doubtless back to the time of Genghis Khan and before, the perpetrators of atrocities have excused their actions with some variation on that theme. Many people dismiss that excuse; they feel that the people involved in such horrors must be sadistic brutes not typical of the human race and comfort themselves with the secure knowledge that they would have the will and strength to refuse to obey such orders. Those comforting beliefs are shattered by Professor Milgram's account of his experiments at Yale during the 1960s. In the tests, subjects recruited from the general public to take part in what they believed to be a learning experiment were placed in a situation where they were required, under the orders of the "experimenter", to administer severe electric shocks to someone they thought to be another unsuspecting recruit for the learning experiment. Their willingness to do so is astonishing, and provides a new basis for understanding, if not excusing, the behaviour of people "just obeying orders".

Most of this book is taken up with descriptions of the various forms of the experiment and the responses of the subjects. Put baldly, it seems astonishing that anyone participated at all. Each volunteer was paired with an actor who was to be the victim in the experiment, and a rigged lottery ensured that the subject became the "teacher". The rationale of the test, as explained to him, was that the "learner" was to be encouraged to remember word pairs in a list by administration of electric shocks of increasing severity every time he made an error. The teacher had to administer these shocks while the genuine experimenter acted as the voice of authority. Many people were quite happy to administer what they genuinely believed to be shocks of up to 450 volts, while the learner screamed, protested, demanded to be released from the experiment and finally fainted.

Even when the teacher protested to the experimenter about the situation,

Fate, time, occasion, chance and change

Cartoon in *The Comic Muse*, July 18 1863, of the proposed removal of the Natural History collections to South Kensington (in fact not moved until the 1880s).

It hasn't always been 'all change' at the British Museum, but as readers of Edward Miller's scholarly and readable history (*That Noble Cabinet*, Deutsch, London, February 1974; £4.80) of the museum will soon discover, this famous institution has not been blessed with a particularly peaceful existence. For the first 150 years of the museum's life, since its foundation by Act of Parliament in 1753, if there weren't squabbles between the government, the trustees and the staff about money and buildings, there were worries about staffing, space and facilities; and in Victorian times especially there also seem to have been endless bickerings between certain of the senior staff.

The museum, however, weathered all the storms—including a heavy battering during the Second World War—and is all set to face the next

upheavals when, if present plans materialise, the library will be severed from the other departments and uprooted into new buildings. The museum was founded mainly as a department of natural history; ironically, it was this department—despised by the great librarian Panizzi (the architect of the present reading room)—which was the first major section to be severed physically if not completely emotionally from Bloomsbury when it was moved in the 1880s to Waterhouse's new buildings in South Kensington.

Miller—himself a museum man—has written a fascinating tale. There is no doubt that the BM has been favoured with more good luck, and loyalty from benefactors and staff, than its trustees and the British nation have at times deserved.

SARAH BUNNEY

he could usually be encouraged to carry on for some time, administering greater and greater shocks by such responses as "The experiment requires you to continue" or "It is absolutely essential that you continue". The voice of authority carried remarkable weight. So much so that the early simple versions of the experiment proved useless in defining exactly where people would draw the line. From having the 'victim' out of sight in the next room, successive modifications of the experiment eventually lead to physical contact, when the teacher had to hold the protesting learner in con-

tact with the plate supposedly giving shocks. And some people, acting under orders, carried out their duties up to the 450 volt level clearly labelled with "Danger Severe Shock". It is natural to ask how careful the experimenters were in their investigation—can their results be extrapolated to normal conditions? The answer seems to be yes. Over several years variations on the experiment were tried in which the "authority" was no longer respectable Yale University but a seedy (and fictitious) firm of "Research Associates", operating from a run down neighbourhood. Various permutations

on the roles were also investigated, with in some cases two experimenters giving conflicting orders, in others the experimenter himself offering to be the 'learner' to show how harmless everything was and then screaming to be let out, and so on. The results seem clear: given a defined chain of command and a guiding plan which must be obeyed most subjects were prepared to administer severe pain in a futile 'experiment' even when it caused them considerable emotional distress. In the most extreme cases, people were found who pressed on even when they thought the 'victim' had a weak heart and might be dying.

Thus far, the book is compelling reading and provides food not just for thought but for self analysis, but when Professor Milgram feels the need to produce theories to explain the behaviour he is on much weaker ground. This is as much because of the state of the art of psychology as through any fault of his, but it is a pity that able experimenters should so often feel the need to be theoreticians as well. The latter part of the book is, however, prevented from being in any sense an anticlimax by a double sting in the tail—an epilogue about My Lai, and an appendix discussing the ethics of carrying out the experiment at all.

MARY GRIBBIN

Eyes of the aged

The Human Lens in Relation to Cataract. Pp. x+324. (Ciba Foundation Symposium 19, New Series.) (Elsevier/Excerpta Medica/North-Holland, Associated Scientific Publishers: Amsterdam, London and New York, 1973.) Dfl. 43.50; \$16.70.

ALTHOUGH the surgery of cataracts figures prominently in many ophthalmic practices, clinical research has been mainly concerned with the technological problems of avoiding the post-operative complications. The relative success of modern cataract surgery may have inhibited to some extent the need for research into the mechanisms responsible for, and the changes which occur as a result of, the development of lens opacities in the aged. There cannot be complete complacency on the clinical side, however, as the patient after a successful lens extraction is nevertheless challenged by a series of problems in achieving 'better sight'. The need for research at a more fundamental level is thus of great importance.

Publication of this volume was timed to coincide with the retirement of Dr A. Pirie from the post of Reader to the University of Oxford, which she has held with distinction from 1948 to 1973, and records the proceedings of a symposium on the human lens

in relation to cataract under her chairmanship. In a series of papers followed by wide ranging discussions investigators eminent in their respective fields present their current views arising from investigations into the physical, biochemical, immunological and epidemiological changes which occur in the ageing lens. In subsequent sections it is perhaps unfortunate that the problem of iatrogenic cataracts did not receive more attention, but this was more than offset by a communication indicating that at least in certain parts of the world the age at which cataracts develop in populations depends on the geographical habitat.

This volume will be of value to cataract surgeons who wish to expand their knowledge of the subject beyond the confines of operative technique, and provides an up-to-date review of concepts and investigation techniques for laboratory workers engaged in research on lenticular opacities in the aged.

J. C. DEAN HART

Ions enter crystals

Channeling: Theory, Observation and Applications. Edited by D. V. Morgan. Pp. xii+905. (Wiley: London and New York, November 1973.) £11.75.

THE discovery in 1965 that under certain conditions fast ions from nuclear particle accelerators could penetrate to anomalously great depths in single crystals came as something of a surprise to physicists. It was not that any new principle was involved but simply that the passage of fast ions through solids had been well studied for some 70 years and it was not to be expected that a phenomenon as striking as channelling could have avoided detection for so long. This greatly increased penetration occurs when the charged particles travel along the directions of the strings of atoms which make up the crystal lattice, for in these directions the particles can travel freely in the open channels between the atoms with little energy loss. In the past eight years there has been a considerable amount of research on the channelling effect and the principal features are now well understood. Since the effect is beginning to find a number of applications the appearance of a comprehensive treatment is both welcome and timely.

The first half of the book is devoted to discussing the fundamental aspects of channelling and of the corresponding blocking phenomenon which gives rise to the distinctive pattern of ions backscattered by single crystals. Classical models provide a good account of these processes and computer simulation has been successfully employed for predicting the trajectories of ions

in crystals. With increasing accuracy of measurement, however, the use of a wave description may become necessary as in the case of channelling of electrons.

The second half of the book contains accounts of a number of the applications in which the phenomenon has been used. Thus since the blocking process depends sensitively on the structure of the solid it can be used for crystallographic analysis, the pattern immediately leading to the identification of the principal planes and axes of the crystal. Again impurities embedded in otherwise perfect crystals obstruct the free passage of the channelled ions and the nature and location of these impurities can be determined by the change in the pattern of the scattered ions. This technique of atom location is already finding many uses and includes the fields of radiation damage, surface physics and semiconductor technology, each of which is discussed at some length.

One historically interesting application lies in the field of nuclear physics and is for measuring time intervals as short as 10^{-18} s; this was devised in 1960 by Dr P. B. Treacy, five years before the phenomenon of channelling had been discovered. The principle of the method was to observe the distance travelled by an excited nucleus in a crystal in the interval between excitation and disintegration. Dr Treacy's assumption was that the decay products would have a greater chance of escaping from a crystal if the nucleus disintegrated at a point in a channel rather than at the lattice point where it was excited. His experiment proved abortive owing presumably to the poor quality of his crystals and no effect was seen. Some years later, however, when the channelling phenomenon was known, this application was independently proposed by other authors and shown to work. It has now become an established technique and some beautiful experiments have been carried out using it.

The whole field of channelling is excellently described in this book. Its multiple authorship ensures that the chapters on the different aspects of the field bear the stamp of authority and yet they are sufficiently linked together to make a coherent whole without destroying the pleasant idiosyncrasies in style of the individual authors; the editor is to be congratulated on his successful blending together of the component parts. It is informative, stimulating and well presented. As a library book it is likely to remain of value for some time and should be available to all. It will be of special interest to those working in the fields of solid state physics and of the science of materials.

M. A. GRACE

Resource Recovery and Conservation

An International Journal

Editors

Aims and Scope

The Journal is dedicated to detailed and comprehensive investigations of the interdisciplinary aspects of resource recovery and conservation. Resource recovery is recovery of materials and energy resources from wastes now destined to disposal. The wastes may be from household, commercial, or industrial sources and the recovery may be for reuse or recycling. Resource conservation is by appropriate management of natural resources, including implementation of public policies for conservation, and management of process and product design, fabrication, and production for more efficient utilization of materials. Resource recovery from wastes is one method of conservation. Implementation of resource recovery and conservation as a positive policy by the public or private sectors requires economical processes, scientifically based, soundly engineered, and properly planned for public acceptance.

The range of application to resource recovery is interdisciplinary and broad. Thus the aim of the journal is to act as an integrated forum, and a medium for the communication, information and guidance of experts from all over the world on the design, planning, and implementation of recovery and conservation.

Type of contribution

Original papers not previously published

Review articles

Short communications

Contributions may emphasize any of the aspects mentioned above as well as technological or institutional methodology. The latter includes politics, resource management and allocation, social and legal aspects. The writing style and level of presentation should be directed at a knowledgeable audience skilled in the specific subject or a related aspect of resource recovery.

Publication Schedule

RESOURCE RECOVERY AND CONSERVATION
will be published in quarterly issues, one volume per year,
the first of which is scheduled to appear in October 1974.

Subscription Information

Subscription price:

Dfl. 87.00 (about US\$ 33.50) per volume,
plus Dfl. 8.00 (about US\$ 3.00) for postage.

Specimen copies
will be made available
upon request

announcements

In the recently announced Honours List, **Sir John Wolfenden**, formerly chairman University Grants Committee and Director British Museum was made a Life Peer; **W. F. Anderson**, David Cargill Professor of Geriatric Medicine, University of Glasgow; **S. G. Clayton**, President, Royal College of Obstetricians and Gynaecologists; **A. F. Huxley**, Royal Society Research Professor, University College, London; **W. L. M. Perry**, Vice-Chancellor, The Open University; and **D. H. Wilkinson**, Professor of Experimental Physics, University of Oxford, were made Knights Bachelor.

Awards

The Society for Analytical Chemistry announces the **Robert Boyle Essay Awards**. (Entrants must be under 20.) For details write to: The Society for Analytical Chemistry, 9/10 Savile Row, London W1X 1AF.

Appointments

W. F. Vinen has been appointed to the Poynting Chair of Physics at the University of Birmingham.

D. R. Bates has been elected a Foreign Honorary Member of the American Academy of Arts and Sciences for his work on the study of the Earth's atmosphere.

William Lyall Ford has been appointed Professor of Experimental Pathology at the University of Manchester.

Ian Briercliffe Houston has been appointed to the additional Chair of Child Health at the University of Manchester.

Jean Kennedy McFarlane has been appointed Professor of Nursing at the University of Manchester.

J. Wiegold has been awarded a Personal Chair by the University of Wales.

Errata

In the article "Formation of methylmercury in a terrestrial environment" by W. F. Beckert *et al.* (*Nature*, **249**, 674; 1974) the units given in paragraph 3, lines 4 and 5 should be . . . 1 mCi $^{203}\text{Hg m}^{-2}$ and 2–20 Ci g^{-1} respectively.

In the article, "Palatability dynamics of cardenolides in the monarch butterfly" by L. P. Brower (*Nature*, **249**, 280; 1974) Table 2 contained several errors and the following corrections should be made: California butterflies, line one, number of birds should read 9†; line eight, absorbance range of subsample should read 0.320 to 0.399||; Massachusetts butterflies, line four, number of birds should read 10¶; Totals should read Males 186 and Females 169.

International meetings

September 19, **Thermodynamics and Fluid Mechanics/Environmental Science and Technology Joint Conference** (A. J. Tugwell, Groups Department, The Institution of Mechanical Engineers, 1, Birdcage Walk, Westminster, London SW1).

September 19–20, **Action of Drugs on Vertebrate Cells in vitro** (Dr M. Balls, School of Biological Sciences, University of East Anglia, Norwich NOR 88C, UK).

September 20–22, **Science, Technology and Society in Victorian England** (The Centre for Continuing Education, Education Development Building, University of Sussex, Brighton BN1 9RG, UK).

September 20–22, **1974 Annual Conference of the Education Group of the Institute of Physics** (Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1X 8QX).

September 22–24, **Rosenhain Memorial Conference** (The Conference Secretary, Dr D. E. Miles, Division of Materials Applications, National Physical Laboratory, Teddington, Middlesex, UK).

September 22–25, **International Symposium on the Electro-optical Properties of Macromolecular Solutions** (Dr C. Houssier, Laboratoire de Chimie Physique, Université de Liège au Sart-Tilman, B-4000 Liège, Belgium).

September 22–25, **48th Annual Conference of Aslib** (The Conference Organiser, Aslib, 3 Belgrave Square, London SW1X 8PL).

September 22–28, **Short Course on Environmental Health Engineering in Hot Climates and Developing Countries** (John Pickford, University of Technology, Loughborough, Leicestershire, LE11 3TU, UK).

September 23–26, **2nd Meeting of the European Geophysical Society** (Professor A. Marussi, Instituto di Geodesia e Geofisica, Università Degli Studi, Trieste, Italy).

September 23–26, **International Symposium on Contamination Control** (ICCCS, 6 Conduit Street, London W1R 9TG).

September 23–27, **9th World Energy Conference** (E. Ruttle, Secretary-General, World Energy Conference, 5 Bury Street, St. James's, London SW1Y 6AB).

September 23–27, **6th International Symposium on Problems of Listeriosis** (Dr Malcolm Woodbine, Microbiological Unit, Department of Applied Biochemistry and Nutrition, Faculty of Agricultural Science, University of Nottingham, Sutton Bonington, Loughborough, LE12 5RD, UK).

September 23–27, **8th International Conference on the Properties of Water and Steam** (Conference I.A.P.S., Secrétariat, c/o S.F.T., 28 rue de la Source, 75016 Paris, France).

September 23–27, **6th International Congress of Infectious and Parasitic Diseases** (6th International Congress of Infectious and Parasitic Diseases, 01-201 Warszawa, Wolska 37, Poland).

September 23–27, **22nd Symposium of Vertebrate Palaeontology and Comparative Anatomy** (D. W. Yalden, Department of Zoology, The University, Manchester M13 9PL, UK).

September 23–October 3, **NATO Advanced Study Institutes Programme** (Miss C. H. Borrey, Institut de Recherche Interdisciplinaire, School of Medicine, Boulevard de Waterloo, 115, B-1000 Brussels, Belgium).

September 24, **Growth of Crystals from Biological Molecules** (Professor A. C. T. North, Astbury Department of Biophysics, University of Leeds, UK).

September 24–26, **5th International Symposium on Gallium Arsenides and Related Compounds** (Dr R. Veilex, Fifth International Symposium on Gallium Arsenide and Related Compounds, LEP, 3 avenue Descartes, F-94450 Limeil Brévannes, France).

September 24-26, **Radioimmunoassay and Related Topics in Clinical Biochemistry** (Mr J. Maxwell Jones, LKB Instruments Ltd., 232 Addington Road, Selsdon, South Croydon, Surrey CR2 8YD, UK).

September 24-27, **CAD 74 International Conference and Exhibition on Computers in Engineering and Building Design** (M. I. Dawes, IPC House, 32 High Street, Guildford, Surrey GU1 3EW, UK).

September 25, **Sounding Rockets and Experimental Results** (L. J. Carter ACIS, The British Interplanetary Society 12 Bessborough Gardens, London SW1V 2JJ).

September 25-29, **10th International Congress of Herpetology** (Dr K. Klemmer, Deutsche Gesellschaft für Herpetologie und Terrarienkunde, Senckenberganlage 25, Frankfurt (Main)-1, Germany).

September 26-27, **X-ray Astronomy by Rockets and Satellites** (L. J. Carter ACIS, The British Interplanetary Society, 12 Bessborough Gardens, London SW1V 2JJ).

September 27, **Annual General Meeting of the Bone and Tooth Society** (Royal Dental Hospital, 32 Leicester Square, London WC2).

September 28, **Nutrition Society Meeting** (Dr J. D. Sutton, Hon. Programmes Secretary, National Institute for Research in Dairying, Shinfield, Reading RG2 9AT, UK).

September 30-October 1, **Meeting of the Executive Committee of the International Union of Pure and Applied Physics** (Associate Secretary General of IUPAP, c/o Institute of Theoretical Physics, Fack, S-402 20 Göteborg 5, Sweden).

September 30-October 4, **2nd Symposium on Neutron Dosimetry in Biology and Medicine** (Symposium Secretariat, Gesellschaft für Strahlen- und Umweltforschung mbH, D-8042 Neuherberg/Munich, Ingolstädter Landstr. 1, Federal Republic of Germany).

September 30-October 5, **25th International Astronautical Congress** (International Astronautical Federation, 250 Rue Saint-Jaques, 75005 Paris, France).

APPOINTMENTS VACANT

DIRECTOR

The Jackson Laboratory invites applications for the position of Director of the Laboratory, which will become open on October 1, 1975. Qualified applicants are invited to submit a curriculum vitae and summary of experience to one of the following:

Dr James D. Ebert, Chairman, Search Committee, Marine Biological Laboratory, Woods Hole, Massachusetts 02543;

Dr James F. Crow, Member, Search Committee, Department of Medical Genetics, University of Wisconsin, Madison, Wisconsin 53706;

Dr Douglas L. Coleman, Secretary, Search Committee, The Jackson Laboratory, Bar Harbor, Maine 04609.

AN EQUAL OPPORTUNITY EMPLOYER.

(3)

PROFESSOR OF BIOMETRY OR BIOSTATISTICS

Applicants are invited to apply for a new senior faculty position in the Statistical Science Division, Department of Computer Science, SUNYAB, starting in September 1975. Applicants should have an outstanding record of research, training and collaboration in the Health and Statistical Sciences. Responsibilities include teaching, developing curriculum for undergraduate and graduate courses in Biometry and Statistical Science for specialists and non-specialists, and active participation in the collaborative activities within the Statistical Laboratory. Applications from women and minority candidates will be especially welcome. Please send curriculum vitae to:

Professor Marvin Zelen, Chairman
Search Committee
Statistical Laboratory
SUNY at Buffalo
4230 Ridge Lea Road
Amherst, New York 14226

(8)

RESEARCH POST AT THE OXFORD HAEMOPHILIA CENTRE

Applications are invited from medically qualified graduate scientists with some experience of research in some aspect of haemostasis for appointment as a member of a small team of Medical Research Council staff working at the Oxford Haemophilia Centre, under the direction of Dr Rosemary Biggs. The successful candidate will be expected to co-operate with other members of staff on projects already progressing at the Centre and to initiate a research project or projects in the general field of interest of the work at the Centre. The work of the M.R.C. staff is integrated with that of the N.H.S. Clinical Unit, many projects being undertaken jointly, and an Honorary Clinical contract with the United Oxford Hospitals may be sought at a level appropriate for the successful candidate. The M.R.C. and N.H.S. staff also work in close co-operation with the staff of the Lister Institute Plasma Fractionation Laboratory and joint research projects may be planned. The appointment will be to the M.R.C. staff on the appropriate scientific grade and will initially be for a period of five years with the possibility of renewal at the end of this period. Superannuation provision.

Applications should be addressed to Dr Rosemary Biggs, Director, Oxford Haemophilia Centre, Churchill Hospital, Headington, Oxford OX3 7LJ.

(2)

Senior Toxicologist

The Toxicology area of the Research Department is expanding and an experienced Toxicologist is required to take charge of a new section. This will entail the planning, conduct and assessment of acute and chronic tests in rodents and some general pharmacological investigations. The person appointed will be expected to maintain close liaison with other staff concerned in the safety evaluation of new Medical, Animal Health and Crop Protection products, and to contribute towards technical documents for registration of such products in the U.K. and overseas. Publication of results and attendance at scientific meetings are encouraged.

The modern, well-equipped research laboratories and associated facilities are located in Nottingham.

Applicants must have a good honours degree in pharmacology or relevant biological science and, preferably, a postgraduate qualification. Experience of working in Toxicology and a high standard of scientific report writing are essential.

Starting salary is negotiable and will reflect qualifications and experience. Conditions of employment are attractive and include good profit sharing and contributory pension schemes. Assistance with relocation expenses will be granted where appropriate.

Please write to:—J. F. Pattison, Employment Services,

The Boots Company Ltd.,
Station Street,
Nottingham NG2 3AA.

(9)

The University of Stellenbosch
Republic of South Africa

Senior Lectureship in Chemical Engineering

Applicants must have industrial and/or lecturing and/or research experience, and must indicate the direction(s) in which they specialise or their field(s) of research. The scope of work in the department is such that an engineer with almost any specialised interest in Chemical Engineering, will be able to lecture on subjects within his particular field of interest. Duties must be assumed on January 1, 1975, or as soon as possible thereafter.

Initial salary will be negotiated between £4,540 and £5,813 per annum, approximately, commensurate with experience and qualifications. Senior Lecturers in the Faculty of Engineering are permitted, on a limited scale, to carry out private

consultation work of a specialised nature.

In addition, the University offers a medical aid scheme, pension fund, group life insurance, housing subsidy, annual leave bonus, generous leave benefits and contributes towards moving costs of newly appointed staff. Applications, giving full details of research or teaching experience with certified copies of recent testimonials and the names and addresses of at least three referees, as well as present salary, age, marital status and general health condition, should, within one month of this advertisement, reach the Registrar (Academic), University of Stellenbosch, Republic of South Africa.

(53)

Senior Pharmacologist

Our client is a major British Research Organisation with extensive expertise in the field of biomedical sciences. Its function is to employ the latest skills, facilities and equipment to carry out research projects under contract for industry, government agencies and international bodies.

The laboratories are already well established, and are committed to a substantial growth and development programme over the next few years. In this connection we seek an experienced pharmacologist to spearhead the existing pharmacology projects, and also to identify and exploit new business opportunities in the UK and overseas.

Much importance is attached to publicising the specialised techniques developed in the unit, which currently include facilities for advanced psychopharmacological studies in primates, sensitive test systems for assessing the abuse-potential of new drugs and cardiovascular pharmacology. The successful candidate will be encouraged to develop interrelationships with other specialist research units, both within the organisation and outside it.

Applicants should be graduates in pharmacology or a closely related subject, ideally with a Ph.D. and several years' post-graduate experience in industrial pharmacology. A specific knowledge of behavioural pharmacology would

be of particular interest to our client. In addition, candidates should have an adaptable and outgoing personality, with the ability to sell their ideas and services.

Salary is negotiable within wide limits and will reflect the importance of this position. Benefits include a progressive contributory pension scheme with free life insurance, four weeks holiday and generous assistance with relocation expenses.

The laboratories are situated in pleasant countryside near a major University city.

Please write in complete confidence for an application form and further literature, or 'phone if you would like to discuss the position:

Mr. R. A. Forbes-Leith, Talentmark Limited,
King House, 5/11 Westbourne Grove,
London W2 4UA. Tel: 01-229 2266.

Biomedical and Scientific Consultants

(12)

THE UNIVERSITY OF NEWCASTLE UPON TYNE CHAIR OF PHYSICS

Applications are invited from experimental physicists for the Chair which was held until his death by Professor W. R. Hindmarsh. This is the third Chair in the School of Physics (the others being Geo- and Planetary Physics, and Theoretical Physics). Salary in accordance with the Professorial Scale (£5,625 by £96 to £5,721 by £195 to £6,501) with membership of F.S.S.U.

Further particulars may be obtained from the Registrar, the University of Newcastle upon Tyne, 6 Kensington Terrace, NE1 7RU, with whom applications (15 copies), giving the names of not more than three referees, must be lodged not later than August 31, 1974. (Applicants from outside the British Isles may submit one copy only.) (5)

SIR GEORGE WILLIAMS UNIVERSITY

MONTREAL, QUEBEC, CANADA DEPT. OF BIOLOGICAL SCIENCES THREE FACULTY POSITIONS

Three faculty positions available, July 1, 1974: 1 Associate Professor (\$15,400 to \$17,000), 2 Assistant Professors (\$12,000 to \$15,00) depending upon experience and qualifications. Research oriented persons qualified to teach in one or more of the following areas will be considered: Embryology, Plant Ecology, Biostatistics, Introductory Biology, Ph.D. required. Send resume and names of three references to: Dr. H. Enesco, Chairman, Dept. of Biological Sciences, Sir George Williams University, Montreal, Que. H3G 1M8. (10)

THE UNIVERSITY OF MANCHESTER LECTURER IN BOTANY

Applications invited for this post. Candidates should have special interests in taxonomy and biosystematics. Salary scale p.a.: £1,929 to £4,548 (under review), but initial salary will not exceed £2,388 p.a. F.S.S.U. Particulars and application forms (returnable by July 20th) from the Registrar, The University, Manchester M13 9PL. Quote ref: 136/74/N. (15)

FOOD HYGIENE LABORATORY

A.I.M.D.T. with experience in Bacteriology. The laboratory is concerned with the routine surveillance of foodstuffs and the investigation of problems associated with food hygiene and food poisoning. The successful applicant will be encouraged to take part in research projects which include work on the many types of organisms now associated with food poisoning.

The laboratory offers good facilities for study towards the special examination in bacteriology. Further information or arrangements to visit the laboratory can be made by telephoning the Head Technician, 205 7041, Extension 38. Application forms can be obtained from the Personnel Officer, Central Public Health Laboratory, Colindale Avenue, London NW9 5HT. (6)

UNIVERSITY OF ABERDEEN SENIOR LECTURESHIP IN ANATOMY

Applications are invited for above post. The successful applicant will be responsible for teaching and supervising both medical and science students. Good facilities for research. Possession of a medical degree desirable but not essential. Post tenable from October, 1974, or as soon as possible thereafter. Salary on scale £4,707 to £5,844 per annum with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (6 copies) should be lodged by August 3, 1974. (25)

University of London CHAIR OF ENVIRONMENTAL GEOLOGY AT CHELSEA COLLEGE

The Senate invite applications for this newly established Chair. The person appointed will be asked to collaborate closely with other Departments in the Environmental Sciences, and will play a leading part in developing both specialised and interdisciplinary studies at First and Higher Degree levels. Initial salary to be agreed but not less than £5,973 a year, plus £162 London Allowance. Applications (10 copies) should be received not later than July 23, 1974 by the Academic Registrar, (N) University of London, Senate House, WC1E 7HU, from whom further particulars may be obtained. (39)

AVON AREA HEALTH AUTHORITY (TEACHING)

BRISTOL HEALTH DISTRICT (TEACHING)

RADIOTHERAPY CENTRE WORKSHOP

Technician Grade IV or V

This interesting post includes the construction and development of apparatus for patient treatment and working on the mechanics of highly complex treatment machines. Would suit a Tool-maker or Instrumentmaker. Qualifications—Engineering Apprenticeship and either City and Guilds Final, O.N.C., H.N.C. or H.N.D. Salary Grade V £1,308 to £1,677 or Grade IV £1,530 to £1,953, depending upon qualifications.

Student Technician

Aged between 16 and 18 years old to train in the Bristol Health District (Teaching) Radiotherapy Workshop. A very interesting post, the work involves precision engineering and plastic techniques. Day release for further education. Someone with 4 'O' levels or equivalent preferred.

Applications, with the names and addresses of two referees and full details, should be sent to the Administrator, Radiotherapy Centre, Horfield Road, Bristol BS2 8ED. (45)

UNIVERSITY OF THE WEST INDIES BARBADOS

Applications are invited for (a) SENIOR LECTURER or (b) LECTURER IN BIOLOGY, tenable not later than 1st October, 1974. Appointee should have suitable qualifications in Biological Science including Biochemistry and/or Physiology.

Salary scales: (a) BD\$18,108-26,730 p.a. (b) BD\$13,200-20,904 p.a. (£1 sterling=BD\$4.8). F.S.S.U. Unfurnished accommodation at rent of 10% of salary for maximum of three years, thereafter 20% of salary paid in lieu of housing. Family passages. Detailed applications (6 copies), including a curriculum vitae and naming 3 referees should be sent by air mail, as soon as possible to the Registrar, University of the West Indies, Mona, Kingston 7, Jamaica. Detailed particulars are available and should be obtained from the same source when an application is made. (22)

NATURE CONSERVANCY COUNCIL DIRECTOR — ENGLAND

£7,279-£8080 (currently under review)

Applications are invited for the new post of Director England of the Nature Conservancy Council (NCC). This post offers outstanding opportunities for a candidate with management ability and scientific understanding and a concern to conserve the wildlife of the country.

The Director will have authority delegated to him by the Director of the NCC for activities in England. He will work closely with the Chairman of the Council's Statutory Advisory Committee for England and will contribute towards the Council's policies as a member of the Great Britain Board of Management.

The Director England will have his own Headquarters and will direct six Regional Officers with responsibility for a staff of 160 and be responsible for 67 National Nature Reserves and 2,010 Sites of Special Scientific Interest. He must maintain high level contact with Central and Local Government Departments and Agencies, land managers and users, and a wide range of scientific, professional and voluntary bodies.

The post is graded Deputy Chief Scientific Officer. Candidates should have appropriate scientific qualifications and must have proven capacity for management and liaison.

Initially the post will be based in London with the possibility of relocation at a convenient site outside London. The successful candidate should take up office as soon as possible.

Interviews will be held in London on 8 August.

Application forms are available from Establishments (S), Nature Conservancy Council, 19 Belgrave Square, London SW1X 8PY.

Closing date for completed application forms: 22 July 1974. (20)

THE UNIVERSITY OF LEEDS PROCTER DEPARTMENT OF FOOD AND LEATHER SCIENCE

Applications are invited from chemists, biochemists, biophysicists, or other suitably qualified graduates for the post of LECTURER IN FOOD SCIENCE. Evidence of ability in research is required. The successful candidate will have teaching responsibilities in food chemistry. He will join the new Head of Department, Professor D. S. Robinson, in establishing research into the relation between chemical structure and function in foods, in particular in relation to proteins. An ability to acquire and apply many different specialised techniques to the study of protein function would be of advantage.

Salary on the scale £1,929 to £4,548 (under review).

Forms of application and further particulars from the Registrar, The University, Leeds LS2 9JT (please quote 40/8/D). Closing date August 30, 1974. (29)

UNIVERSITY OF THE WEST INDIES JAMAICA

Applications are invited for the posts of SENIOR LECTURER and LECTURER IN THE DEPARTMENT OF PHYSIOLOGY. Appointees should possess a medical qualification or degree in Physiology. The duties will include lecturing and demonstrating in experimental and human physiology. Duties to be assumed soonest. Salary scales: (Medically qualified) Senior Lecturer J\$10,992-14,472 p.a. Lecturer J\$7,860-10,752 p.a. (Non Medically qualified) Senior Lecturer J\$10,992-14,472 p.a. Lecturer J\$7,860-10,752 p.a. (£1 sterling = J\$2.20). F.S.S.U. Unfurnished accommodation will be let by the university at a rental of 10% of salary. Family passages; triennial study leave. Detailed applications (6 copies) including a curriculum vitae and naming 3 referees should be sent as soon as possible to the Registrar, University of the West Indies, Mona, Kingston 7, Jamaica. Further particulars are available from the same source and should be obtained before an application is made. (21)

CENTRAL BIRMINGHAM HEALTH DISTRICT QUEEN ELIZABETH HOSPITAL, BIRMINGHAM B15 2TH BASIC GRADE BIOCHEMIST

required in Clinical Chemistry Department. This is a new post, for two years in the first instance, in which at least half the time will be devoted to a research project.

Job description and application form from Assistant Secretary (Personnel) at the above address. Closing date for applications July 31. (30)

Scientific Officers

Applications are invited for pensionable posts in the following Research Centres of the Department of Agriculture, Northern Ireland.

Agricultural and Food Chemistry Research Division

To join a team engaged in research projects in the various aspects of agricultural and food chemistry, plant and animal nutrition and plant and animal biochemistry.

Field Botany Research Division

To join a team engaged in research on growth and physiology of crops especially grasses, mainly in glass houses and controlled environmental growth rooms.

Agricultural and Food Bacteriology Research Division

To join a team engaged in research and investigational work into the bacteriological problems of the agriculture and food industry, including the microbiological examination of various foods and materials.

Fisheries Research Laboratory, Coleraine

Two officers are required; one to cover duties in the Department's angling development programme, which will include surveys of lakes and rivers. Laboratory work will include the examination of invertebrate fauna and fish samples and subjecting them to appropriate analyses.

The duties attached to the other post involve assessing salmonid production and populations in tributary rivers to Lough Neagh and especially in the Foyle system. In particular, studies of variations in annual recruitment and survival rates are required.

Candidates must be under 27 years of age on December 31, 1974 and have a degree, HNC or equivalent qualification in an appropriate Scientific subject. Applications will also be considered from final year students. Ability to drive and swim is essential for the fisheries post.

Salary scale (under review): £1,600 to £2,544. Starting salary will be related to qualifications and post-qualifying experience.

There are prospects of promotion to Higher Scientific Officer (£2,221 to £2,854), Senior Scientific Officer (£2,798 to £3,895) and Principal Scientific Officer (£3,715 to £4,895).

Please write or telephone for an application form and further information, quoting Ref. SB 172/74/N to the Secretary, Civil Service Commission, Clarendon House, Adelaide Street, Belfast BT2 8ND (telephone 0232-44300, ext. 26). Completed forms must be returned to arrive not later than July 25, 1974.

Applicants should state their preference for a particular Division. (24)

**NORTHERN IRELAND
CIVIL SERVICE**

Biochemist Team Leader

Analyst Team Leader

The Radiochemical Centre has created two posts for qualified scientists with experience in biochemistry and analysis.

The biochemical post calls for the capability of initiating and developing quality control techniques for the radioimmunoassay and biochemical assay of our radiopharmaceuticals.

The analytical post involves the development of chromatographic and other analytical techniques for organic chemicals by modern instrumental methods. A knowledge of statistical quality control techniques is desirable.

Both posts require at least an academic qualification of honours degree standard and relevant experience is essential.

The salary would be a minimum of £2500. Generous leave allowance, contributory superannuation scheme, staff canteen and social club.

The Radiochemical Centre is a world leader in the supply of radiochemicals and radiopharmaceuticals. If you want further information ring Martyn Bishop at Little Chalfont 4444 or write for an application form to

The Radiochemical Centre

Amersham

Bucks

(43)

THE GAMBIA Agronomist

Required by the Department of Agriculture for 2 tours of 12/24 months to assume responsibility for the experimental farm and the Agronomy section involved in field trials of upland crop production of pre-basic and foundation seeds and work on vegetables.

Candidates should have an honours degree in Agriculture or Agricultural Science with at least one year's field experience in agronomic research. Knowledge of Tropical Agriculture would be advantageous.

Salary in the range £2,270 to £4,350 p.a. which includes an allowance, normally tax free, of £1,266 to £2,400 p.a. Terminal gratuity 25% on basic salary only.

For a married man with two children paying tax at the standard rate the total emoluments described above, including gratuity, approximate to a gross (i.e. before tax) UK return of 3,800 to £6,200 and for a single man about £3,300 to £5,700 p.a.

Benefits include: generous leave, paid passages, education allowances, government quarters at reasonable rentals. A car loan of £600 and an Appointment Grant of up to £200 may also be payable.

The post described is partly financed by Britain's programme of aid to the developing countries administered by the Overseas Development Administration of the Foreign and Commonwealth Office.

For further particulars you should apply, giving brief details of experience to:

crown agents

M Division, 4 Millbank, London SW1P 3JD, quoting reference number MID/740611/NF (27)

Guy's Hospital Medical School

Graduate Research Assistant

required in Department of Obstetrics and Gynaecology for research on fat metabolism in pregnancy. Opportunity of higher degree. Experience of techniques of lipid analysis an advantage. Salary in range £1,569 to £1,833 (under review).

Apply in writing, with curriculum vitae, to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT. (36)

UNIVERSITY OF THE WEST INDIES JAMAICA

Applications are invited for the post of LECTURER/ASSISTANT LECTURER IN MATHEMATICS. Applicants should have teaching and research experience in Pure or Applied Mathematics, tenable 1 October 1974. Salary scale: Lecturer J\$6,168-9,768. Assistant Lecturer J\$5,006-5,486 p.a. (£1 sterling = J\$2.20). F.S.S.U. Unfurnished accommodation will be let by the University at a rental of 10% of salary. Family passages; triennial study leave. Detailed applications (6 copies) including a curriculum vitae and naming 3 referees should be sent as soon as possible to the Registrar, University of the West Indies, Mona, Kingston 7, Jamaica. Further particulars are available from the same source and should be obtained before an application is made. (23)

UNIVERSITY OF CAMBRIDGE DEPARTMENT OF PHYSICS

It is intended to appoint a University Demonstrator in the Department of Physics to hold office from October 1, 1974 or as soon after as may be convenient. Two of the research groups in the Department are concerned with the theory of condensed matter and with experimental particle physics using bubble chambers, and preference will be given to candidates with an interest in working in these fields. The teaching duties are not so specialised and importance will be attached to the evidence of teaching ability at an undergraduate level. The appointment will be subject to the Statutes and Ordinances of the University, and will be for three years in the first instance, with the possibility of reappointment for two years. The maximum tenure of a University Demonstratorship is five years.

The pensionable scale of stipends from October 1, 1974, is £2,247 p.a., rising by unequal annual increments to £2,931, or, if the person appointed is ordinarily resident in College, £2,148 p.a. rising by unequal annual increments to £2,832.

Applications (ten copies), together with the names and addresses of not more than three referees, should be sent to the Secretary of the Appointments Committee of the Faculty of Physics and Chemistry, Department of Physics, Cavendish Laboratory, Madingley Road, Cambridge, CB3 0HE, so as to reach him not later than July 29, 1974. (32)

UNIVERSITY OF SUSSEX

LECTURER IN ENVIRONMENTAL STUDIES

Applications are invited for the post of Lecturer in Environmental Studies in the School of Cultural & Community Studies from October 1, 1974. Applicants should be qualified in the biological or social sciences and have a particular interest in Population Analysis and Policy.

Initial salary will be within the range £2,118 to £2,757 per annum on the Lecturer scale (£2,118 to £4,896 per annum) plus Threshold payments and F.S.S.U.

Further particulars and application forms, returnable by July 19, 1974, are obtainable from the Establishment Section, Office of Arts & Social Studies, Arts Building, University of Sussex, BRIGHTON BN1 9QN (Brighton 66755, ext 712, Miss Holland) quoting reference 444/4. (31)

IMPERIAL COLLEGE
DEPARTMENT OF ZOOLOGY
AND APPLIED ENTOMOLOGY

LECTURERS/RESEARCH
FELLOWS IN ZOOLOGY

Applications are invited for the above positions: Preference will be given to candidates with interests in Parasitology (Animal Parasitic Nematodes and their Vectors) and applied Insect Ecology. The initial salary will be in the range of £2,118-£3,285. (Research Fellows) or £2,118 - £4,896 (Lecturers) plus F.S.S.U. and London Allowance (unless based at the field station). The positions are tenable from 1st October or later by arrangement. Further particulars may be obtained from Professor T. R. E. Southwood, Imperial College, Prince Consort Road, London, S.W.7. To whom applications, with the names of two referees, should be sent by 1st August. (59)

THE INTERNATIONAL CENTRE OF
INSECT PHYSIOLOGY AND
ECOLOGY

P.O. BOX 30772,

NAIROBI
Kenya

RESEARCH SCIENTIST
(ENDOCRINOLOGIST)

Ref: Res/74/12

Applications are invited from young scientists with Ph.D. degree or its equivalent.

Requirements: Candidates should have experience in the field of endocrinology and should have a strong background in experimental entomology. Tropical experience will be an advantage.

Responsibilities: The appointee will work on reproduction, development, seasonality, and diapause in the Sorghum Shootfly.

Salary: Will depend on qualifications and experience, but not less than K.Shs.44,000/= per year. Other benefits include ten per cent gratuity of basic salary earned, a housing allowance, and medical insurance.

Applications, in six copies, should give the following information: General education, Professional qualifications, experience, marital status, age, present salary and terms of service, reprints of any published articles, and names and addresses of four referees (including a personal reference). Photostat copies of relevant transcripts, thesis abstracts, and certificates should be enclosed.

Applications should be addressed to:

The Administrative Officer,
ICIPE Research Centre,
P.O. Box 30772,
NAIROBI
Kenya

to reach him before 31st July, 1974.

51

THE QUEEN'S UNIVERSITY OF
BELFAST

Lectureship in
Physical Chemistry

Applications are invited for the above post which is tenable from October 1, 1974 or such other date as may be arranged. Applicants should have some postdoctoral experience, including teaching. Research interests in the fields of polymer chemistry and/or nuclear magnetic resonance spectroscopy would be an advantage. Initial placing, which will depend on experience and qualifications, will be made at one of the first three points on the lecturers' scale, £2,118 to £2,247 to £2,412 rising to £4,896, with contributory pension rights under the F.S.S.U. The appointment will be subject to a period of probation of up to three years in duration. Applications should be received by August 15, 1974. Further particulars may be obtained from the Personnel Officer, The Queen's University of Belfast, BT7 1NN, Northern Ireland.

(Please quote Ref. 74/N.)

(52)

CAMBRIDGE UNIVERSITY PRESS

SENIOR EDITOR
PHYSICAL SCIENCES

The Press requires a senior editor with the ability to expand profitably an important physical science list, covering the entire range from undergraduate textbooks to research monographs. He will be expected to acquire manuscripts within the Press's overall editorial policy; to make and maintain contact with physical scientists in university departments and elsewhere; to establish good relationships with existing and potential authors; to brief production and marketing departments about new books; and to maintain the profitability of the backlist. Qualities required are initiative, judgment and flair, administrative skill, a professional interest in the sciences, a sense of their likely development, and the ability to define and exploit publishing opportunities. Travel, at home and abroad, is part of the job.

Preferred age 25 to 35; degree in one of the relevant sciences; experience desirable in editorial acquisition in the sciences, or in undergraduate teaching.

The starting salary will be fully competitive and is negotiable in the light of age and experience, with regular progression. Location central Cambridge; contributory pension scheme and other benefits; four weeks' holiday and resettlement expenses.

The Press is one of the world's leading scientific publishers. It is a department of the University, and is governed by a committee, the Press Syndicate, appointed by the University. The Publishing Division produces journals, Bibles and nearly 300 new books each year, and there is also a large Printing Division.

Candidates should apply, giving details of age, education, qualifications, career to date and present salary to:

Dr Alan Winter, Publishing Director,
Cambridge University Press,
The Pitt Building,
Trumpington Street,
Cambridge CB2 1RP

(42)

SUPERVISOR
VACCINE PRODUCTION

We need to recruit an additional Supervisor in our Vaccine Department to take charge of all aspects of the production of a new diagnostic reagent for the detection of hepatitis associated antigen.

There will also be opportunities to take part in advanced development work, mainly involving tissue culture techniques, within the department which is 85 strong.

We believe that the post would suit an F.I.M.L.T. or an A.I.M.L.T. (virology) who has microbiological/biochemical experience, and has an interest in production and process development. It would also be suitable for a graduate with a year or two of post-graduate laboratory experience who now wishes to move into a production environment.

We recognise that the work occupies a relatively narrow sphere of activity, but nevertheless is a rapidly evolving discipline.

Our plant and laboratories are situated in a pleasant location on the Kent Coast and we offer the range of fringe benefits to be expected of an expanding, international organisation.

Pfizer

If you feel that you combine the qualities required for production and the inspiration necessary for development work, please write, giving brief relevant details to: J. E. T. Haile, Personnel Department, Pfizer Limited, Sandwich, Kent.

(73)

NATIONAL COUNCIL FOR SCIENTIFIC RESEARCH

Applications are invited from suitably qualified persons for the posts of:

**BUILDING RESEARCH ENGINEER
BUILDING RESEARCH ARCHITECT
BUILDING MATERIALS SCIENTIST**

Applicants for the post of Building Research Engineer must be engineers or technologists or architects with experience in construction research and development. Residential experience in tropical or sub-tropical areas of building would be desirable. The successful candidates will be required to develop a building research and development programme geared to the requirements of the Zambian construction authorities and industry.

Applicants to the post of Building Materials Scientist must be industrial chemists or engineers with wide experience in the production, usage and testing of building materials. The successful candidate will be required to establish a building materials laboratory service which will undertake research and development and give advice on the production and usage of building materials.

Salary according to qualifications and experience on the following salary scales:

Professional Officers	K3240 × 240 — K4440
Senior Professional Officers	K4680 × 240 — K5640
Principal Professional Officers	K5840 × 240 — K6800
Senior Principal Professional Officers	K7000 × 200 — K7600

For Zambians there is a superannuation scheme. Non-Zambians will be paid a gratuity of 25% of aggregate basic salary earned during service of not less than thirty months.

Accommodation will be provided on an economic rental basis but not exceeding 10% of basic salary. Hard furniture will be provided. For Non-Zambians travel and educational allowances are available for minor dependent children attending school outside Zambia.

Applications giving full personal details, qualifications, experience and naming three referees should be submitted to:

The Secretary-General,
National Council for Scientific Research,
P.O. Box CH. 158,
Chelston, LUSAKA, Zambia.

(50)

UNIVERSITY COLLEGE LONDON Chemistry Department TEMPORARY LECTURER

Applications invited for the post of Temporary Lecturer in Inorganic Chemistry. The successful applicant will be expected to carry a normal teaching load and to devote the remainder of his time to research in inorganic chemistry; he will probably have a PhD degree and some teaching experience.

The appointment will start on October 1, 1974 and be tenable on a yearly basis up to a maximum of three years. Salary will be on an appropriate point on the lecturer scale.

Applications giving details of career, qualifications and the names of two referees, as soon as possible to Mr. F. Widdas, Department of Chemistry (N), 20 Gordon Street, London WC1H 0AJ, from whom further particulars may be obtained. (41)

NATIONAL COUNCIL FOR SCIENTIFIC RESEARCH

Applications are invited from suitably qualified candidates for the posts of

CERAMIC SCIENTIST OR TECHNOLOGIST

Applicants for the post of ceramic technologist must have a University degree in ceramic technology or equivalent qualifications. The successful candidate for the post of ceramic technologist will be required to participate in the research programme of the Ceramic and Refractories Development Research Laboratory. A practically minded person is required to meet the challenge of developing ceramic products from Zambian raw materials.

Salary according to qualifications and experience on the scales

Professional Officer	K3,240x240-K4,440
Senior Professional Officer	K4,680x240-K5,640
Principal Professional Officer	K5,840x240-K6,800

There is a superannuation scheme for Zambians. Non-Zambians will be paid a graduated gratuity of 20% to 30% depending on the length of service.

Applications giving full personal details, qualifications, experience and naming three referees should be submitted to:

The Secretary-General,
National Council for Scientific Research,
P.O. Box CH. 158,
Chelston,
LUSAKA.

(48)

Histology Technician

required for Pharmacological and Toxicological Laboratory. Experience essential in the preparation and processing of animal tissues. Good working conditions. Pension and Assurance Scheme. Application forms from: The Secretary, Biorex Laboratories Ltd., Biorex House, Canonbury Villas, London N1 2HB. (71)

NATIONAL COUNCIL FOR SCIENTIFIC RESEARCH

Applications are invited for an immediate vacancy for a **SENIOR PRINCIPAL PROFESSIONAL OFFICER IN ANIMAL PRODUCTION, ANIMAL PRODUCTIVITY UNIT.**

Applicants must hold postgraduate University degrees in agriculture, animal science, veterinary science, or animal nutrition, animal physiology or animal management. Candidates should have extensive practical research experience. The successful candidate will be responsible for developing, in relation to the Animal Productivity Research Programme, policy on animal production research and supervising the work of the Research Unit. He would be required, under the direction of the Council to collaborate with Government Departments and parastatal organisations.

The salary scale is in the range of K7,000 x 200-K7600. A gratuity of 20 to 30 per cent, depending on length of service is paid to non-Zambians. Travel and educational allowances are available for minor dependent children. Comfortable accommodation with basic furniture will be provided at low rental.

Applications giving full personal details, qualifications and experience and naming three referees should be sent to:

The Secretary-General,
National Council for Scientific Research,
P.O. Box CH. 158,
Chelston,
LUSAKA,
Zambia.

(49)

UNIVERSITY OF SOUTHAMPTON DEPARTMENT OF AERONAUTICS AND ASTRONAUTICS RESEARCH ASSISTANT/STUDENT

Applications are invited for the post of Research Assistant/Student for work on the dynamic stability of axisymmetric bodies at high Mach numbers. The work involves the development of a new type of aerodynamic facility and the exploitation of existing equipment for the measurement of dynamic stability derivatives.

Applicants should possess a good honours degree, or the equivalent, in a subject relevant to this research. The salary will depend on qualifications and experience. In the case of a Research Assistant, the salary will be in the range up to £1,750 per annum. The successful applicant will be expected to register for a higher degree.

Applications, including the names and addresses of two referees, should be addressed to the Deputy Secretary's Section, The University, Southampton SO9 5NH, quoting reference Na/182/R. (55)

AGRICULTURAL RESEARCH COUNCIL UNIT OF DEVELOPMENT BOTANY

Applications are invited from **PLANT PHYSIOLOGISTS** and **BIOCHEMISTS** for a two year temporary appointment as a **SCIENTIFIC OFFICER/HIGHER SCIENTIFIC OFFICER** at the Agricultural Research Council's Unit of Developmental Botany to investigate an aspect of the hormonal control of plant growth development. Candidates should hold post graduate qualifications and have some further experience in original research.

Appointment in grade of Scientific Officer £1,707-£2,329 p.a. or Higher Scientific Officer £2,221-£2,854 p.a. Starting salary in accordance with qualifications and experience. At least two years post graduate experience is required for appointment to H.S.O. Superannuation under F.S.S.U. with an allowance of 41% of basic salary to off-set contributions.

The unit is attached to the Botany School of Cambridge University and is under the Direction of Professor P. W. Brian. Applications should be addressed to the Deputy Director, Dr D. J. Osborne, Unit of Developmental Botany, 181A Huntingdon Road, Cambridge, CB3 0DY. (64)

THE
UNIVERSITY OF MANCHESTER
INSTITUTE OF SCIENCE
AND TECHNOLOGY
DEPARTMENT OF CHEMICAL ENGINEERING
Thermodynamics of Liquid Mixtures

Applications are invited from prospective Graduates in Physical Chemistry, Chemical Engineering or related disciplines for research leading to the degree of Ph.D. in the field of thermodynamic and physical properties of fluids. The work is associated with the extensive Distillation and Absorption research carried out in the Department and is supported by the S.R.C. For suitably qualified candidates financial support can be arranged at a level equivalent to S.R.C. studentships. Further details and application forms may be obtained from Professor G. L. Standart, Department of Chemical Engineering, U.M.I.S.T., Manchester, M60 1QD. (60)

BRUNEL UNIVERSITY

DEPARTMENT OF POLYMER
SCIENCE AND TECHNOLOGY

LECTURER

Applications are invited for the post of Lecturer in Polymer Science and Technology to teach polymer processing and polymer physical properties to students studying for degrees in Polymer Technology and Materials Science.

The person appointed will have a good degree in an appropriate discipline e.g. Polymer Technology, and relevant teaching and research or industrial experience. A demonstrated ability to relate polymer studies to the broader study of materials would be a commendation.

Salary scale (from 1 October 1974) £2,118-£4,896 plus £162 London Allowance, with F.S.S.U. Appointment will be made at one of the first three points on the Lecturer scale.

Postcard for application form and further details to Senior Establishment Assistant, Brunel University, Uxbridge, Middlesex UB8 3PH or telephone UXBRIDGE 37188 extension 49. Closing date: 17th July, 1974. (58)

CHELSEA COLLEGE
University of London

The Biophysics Laboratory has a vacancy for a **LABORATORY TECHNICIAN GRADE 2B**. The appointment of a trainee technician would be considered. The work involves research into electrical properties of biological materials and general teaching laboratory duties. Qualifications required are O.N.C. or equivalent, but two A-levels in appropriate Science subjects would be preferable; encouragement will be given for further study. Salary Scale: £1,699 - £1,969 per annum (including London Allowance) of for a trainee £973-£1,426 per annum (including London Allowance). Please write, giving personal details, to Dr. D. Rosen, Biophysics Laboratory, Chelsea College, Manresa Road, London, SW3 6LX. (61)

**AGRICULTURAL RESEARCH
COUNCIL
UNIT OF DEVELOPMENTAL BOTANY**

Applications are invited for a two year temporary appointment as a **SCIENTIFIC OFFICER** at the Agricultural Research Council's Unit of Developmental Botany. The successful candidate would be engaged in a supporting role in a small team engaged in a study of plant nucleic acids.

Applicant should have an honours degree in a biological subject, preferably Biochemistry, and be prepared to work closely with the team leaders. Starting salary, in the range £1,707 - £2,329 p.a. will be dependant upon qualifications and experience. Superannuation with an allowance to offset personal contributions.

Apply giving full details of qualifications and experience to the Secretary, Unit of Developmental Botany, 181A Huntingdon Road, Cambridge CB3 0DY. (63)

Opportunity Overseas

British Solomon Islands Protectorate

FISHERIES OFFICERS

With the Department of Agriculture to assist in the development of improved fishing and storage techniques mainly for commercial purposes; advise, train and supervise supporting staff.

Applicants should have BSc (Biological Science/Zoology/Marine Biology) with experience in fisheries management. Practical experience preferably in a tropical country. Appointment 2 years.

Salary in scale £2,691-£5,834 pa which includes a non-gratuitable allowance payable in the United Kingdom and normally tax-free, in scale £1,560-£3,186 pa. Terminal gratuity 25% of basic salary.

Other benefits include paid leave, free family passages, children's education allowances and subsidised accommodation. A tax free appointment grant of up to £200 and an interest free car purchase loan of up to £600 may be payable in certain circumstances. Applicants should normally be citizens of, and permanently resident in the United Kingdom.

For full details, application form and booklet about the British Solomon Islands, please apply giving age and brief details of qualifications and experience to:—

Appointments Officer:

Overseas Development Administration

Room E301, Eland House,
Stag Place, London SW1E 5DH

(84)

Senior Biochemist

A leading British pharmaceutical Research Organisation has a vacancy for a **Senior Biochemist** to initiate and direct research projects in the areas of pharmacokinetics, drug metabolism, molecular pharmacology and enzymology in association with the design and development of new medicines. Persons with appropriate experience are invited to apply in writing for further details to: The Secretary, Biorex Laboratories Ltd., Biorex House, Canonbury Villas, London N1 2HB, marking the envelope **CONFIDENTIAL**. (72)

An opportunity in PHOTOSYNTHESIS RESEARCH

at post-doctoral level is available immediately at the Department of Biology within a programme sponsored by the Deutsche Forschungsgemeinschaft at the **University of Konstanz Germany**.

The applicant should have the Ph.D. or equivalent qualification and should undertake research in basic biochemical problems of photosynthetic electron transport in green algae.

Scientists who have some relevant research experience are preferred, but also those are encouraged to apply who have a thorough training in plant physiology, biochemistry or possibly organic chemistry and like to work in the field indicated above.

Please send your application, curriculum vitae including details of previous experience, names of two referees, by July 15, 1974, to Professor P. Böger, Unit of Plant Physiology and Biochemistry, University of Konstanz, 7750 Konstanz, POB 733, Germany. (78)

Brixham
Laboratory

Experimental Biologist or Animal Physiologist

We are looking for a person with a good Honours degree and preferably a Ph.D. to work on the investigation of the long term effects of conservative substances, including bio-accumulated materials, found in industrial wastes, on the vital processes of marine organisms.

The work will initially involve the development of suitable laboratory techniques for measuring the non-lethal effects of pollutants. A good knowledge of chemistry is essential.

Please write, giving brief details of education and experience to:

Dr. V. T. J. Schenk, Head Office Services Dept.
ICI Ltd, Fulshaw Hall, Wilmslow, Cheshire.

(102)

THE UNIVERSITY OF SHEFFIELD ACADEMIC DIVISION OF PATHOLOGY

Applications are invited from medically or non medically qualified persons for the following posts:

LECTURER in CHEMICAL PATHOLOGY, tenable from a date to be arranged. Interest in hormonal control of calcium metabolism or the endocrinology of cancer desirable but not essential. Initial salary in the range (clinical) £2,535 to £3,165 on the scale £2,535 to £4,917 or (non-clinical) £2,118-£2,580 on the scale £2,118 to £4,896.

LECTURER in TUMOUR IMMUNOLOGY, a new post tenable from October 1, 1974. Candidates should have experience in immunochemistry or biochemistry. Work will involve characterization and isolation of antigens and marker substances from human tumours. Salary scale (clinical) £2,535 to £4,917 or (nonclinical) £2,118 to £4,896.

Further particulars (state for which post) from the Registrar and Secretary, the University, Sheffield S10 2TN to whom applications (8 copies) should be sent by July 31, 1974. Please note reference R105/G. (47)

UNIVERSITY OF SINGAPORE CHEMISTRY

Applications are invited for teaching appointments in the Department of Chemistry.

Special consideration will be given to those with teaching/research interests in the field of Chemical Engineering and who have appropriate industrial experience.

Salary in the range S\$1,100 to S\$3,500 per month depending on qualifications and experience, and level of appointment offered. A 13th month annual allowance of one month's salary is payable according to University's regulations.

Leave, provident fund, medical, housing and other benefits are available.

Candidates should write to:

The Registrar,
University of Singapore,
Singapore 10.

giving curriculum vitae (bio-data), with full personal particulars, and also the names and addresses of three referees. (91)

BENDIGO INSTITUTE OF TECHNOLOGY PRINCIPAL LECTURER IN ELECTRICAL ENGINEERING

Applications are sought from persons suitably qualified to lead the Department of Electrical Engineering and to complement the experience and interests of the Head of the Mechanical Engineering Department in the development of a degree course which has contributions from both fields of engineering.

The applicant should possess a first degree in electrical engineering, and be able to provide evidence of post-graduate study in the general field of control systems. Practical experience of industrial controls, or their simulation, would be an advantage.

The applicant should have a sound knowledge of the state-function and the classical approaches to control design. Initially, most control course-work would be in the latter topic. The applicant should be willing to lecture in electrical engineering subjects outside the control field.

Salary: £15,260 per annum.

The successful applicant would be expected to take up duty prior to the commencement of the academic year, early March 1975.

The Bendigo Institute of Technology is a College of Advanced Education offering tertiary level degree and diploma courses across a wide spectrum of disciplines. The Institute is pleasantly situated on a new 85 acre campus six kilometres from the city centre. Bendigo, located some 150 kilometres northwest of Melbourne offers a wide range of schooling at primary and secondary levels.

Further particulars are available on request from the Athe Academic Officer, Bendigo Institute of Technology Flora Hill, Bendigo 3550, Victoria, Australia. Closing date for applications is 20 September, 1974. (65)

UNIVERSITY OF SUSSEX SCHOOL OF BIOLOGICAL SCIENCES TEMPORARY LECTURER IN BIOCHEMISTRY

Applications are invited for a temporary lectureship in Biochemistry, tenable for one year from October 1, 1974. Preference will be given to candidates with an interest in protein or RNA metabolism.

Salary will be on the University Lecturer scale with initial placement in the range £2,118 to £3,285 per annum.

Applications including a curriculum vitae and the names of three referees should be sent to the Secretary of Science, Science Office (E), University of Sussex, BRIGHTON BN1 9RH from whom further details can be obtained. (82)

UNIVERSITY OF BIRMINGHAM FACULTY OF MEDICINE AND DENTISTRY DEPARTMENT OF PHYSIOLOGY

Applications are invited for a POST-DOCTORAL RESEARCH FELLOWSHIP to work on problems of nerve-muscle interaction. Candidates should be interested in using morphological techniques while working in close collaboration with physiologists.

Starting salary up to £2,553 p.a. plus F.S.S.U., depending on age and experience.

Applications, with curriculum vitae, naming two referees, should be sent to Professor S. M. Hilton, Head of the Department of Physiology, The Medical School, Birmingham B15 2TJ. (69)

UNIVERSITY OF LIVERPOOL Department of Dental Sciences

Applications are invited from Honours graduates in Biology, Biochemistry or a related subject for a Research Studentship available in the Department of Dental Sciences from 1st October, 1974. The research programme will involve a study on the metabolism of hard tissues with particular reference to the influence of fluoride on the processes involved.

Applications, giving details of age, academic qualifications and experience, together with the names of two referees, should be received as soon as possible by the Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote ref. RV/276112/N. (87)

PHARMACEUTICAL RESEARCH AND DEVELOPMENT

Our extensive research and development laboratories at Loughborough offer an excellent career opportunity for young graduates interested in contributing to our current research programme into respiratory and cardiovascular diseases.

These posts would particularly suit a recent graduate with a good honours degree or equivalent in pharmacology or pharmacy and the enthusiasm and ability to carve out a successful career in a large, progressive research environment.

An attractive competitive starting salary will be offered and excellent conditions of employment include a full range of fringe benefits and opportunities for movement and advancement throughout our R and D function.

Please write with brief details of qualifications held or expected, and information concerning research activities to date:

A.B. Johnston, Fisons Limited, Pharmaceutical Division, Bakewell Road, Loughborough, Leicestershire.

(70)

UNIVERSITY OF MELBOURNE DEPARTMENT OF GEOGRAPHY

The University wishes to fill the CHAIR OF GEOGRAPHY which will become vacant on 1st January 1975, following the retirement of Professor J. Andrews.

SALARY: \$A19,614 per annum.
Further information, including details of application procedure, superannuation, travel and removal expenses, housing assistance, and conditions of appointment is available on request. All correspondence (marked "Confidential") should be addressed to the Registrar, The University of Melbourne, Parkville, Victoria 3052, Australia. Further information is also available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.
Applications close on 30 September 1974.

(74)

THE HANNAH RESEARCH INSTITUTE DEPARTMENT OF APPLIED STUDIES MILK UTILIZATION

Applications are requested for the post of section-head of the milk utilization group within the Department of Applied Studies. This group is presently working on various aspects of heat treatment and stability of milk proteins, the physical properties of milk fat and the deterioration in the manufacturing properties of milk consequent upon storage at refrigeration temperatures. Applicants should be qualified in chemistry, and some knowledge of the food industry is desirable. They should have considerable research experience and the adaptability to work on various projects of an applied nature.

The appointment will be made at the SSO level (£2,798 - £3,895 plus 4½% compensatory allowance for F.S.S.U. payments), which requires candidates to possess a first or upper second class honours degree and at least four years appropriate post-graduate research experience. Applications, with a full curriculum vitae and giving the names of two referees, should be sent not later than 9th August 1974 to The Secretary, The Hannah Research Institute, AYR KA6 5HL, Scotland, from whom further information may be obtained.

(76)

POST-DOCTORAL Fellow required for Scientific post (MRC Grade II) in the Division of Pathology at the Institute of Cancer Research, to work on aspects of cell differentiation with particular respect to the adrenal gland and its tumours. This work will give experience in methods of tissue culture, steroid analysis and radioimmunoassay. Salary in scale £2,385 - £3,540 plus Stage III and threshold awards. Full applications should be sent as soon as possible, in duplicate, to the Secretary, 34 Sumner Place, London SW7 3NU, quoting ref. 300/G/77.

(80)

Wellcome

Ph.D. for Diabetes Research

The Wellcome Foundation, the £multi-million pharmaceutical company, has interests throughout the world. It is growing rapidly and the majority of the production at Dartford, which is our largest UK site, is for export.

We require a Senior Scientist to augment the current research programme being carried out by the diabetes research unit. This programme involves basic research into diabetes and general metabolic problems.

Candidates, male or female, should hold a Ph.D. in one of the following fields: physical, protein or membrane chemistry. At least three years postdoctoral experience in a biological field and proven ability for originality, are essential.

Salary will be in the range £3,549 to £4,869. Conditions of employment are attractive and include 4 weeks' holiday, excellent pension and life assurance schemes and generous assistance with relocation expenses, where appropriate.

Please write giving brief career details and quoting reference U/397 to the

Site Personnel Officer (CS),
The Wellcome Foundation Limited,
Temple Hill,
Dartford, Kent.

(95)

ENTOMOLOGIST—

Agrochemical Research

Fisons Agrochemical Division, one of the major manufacturers of chemicals for crop protection, are expanding their programme of Research and Development. To satisfy part of our needs, we now wish to appoint a Senior Research Assistant in the Biological Screening Department of our Chesterford Park Research Station, near Saffron Walden, Essex.

Ideally, we are seeking either a young graduate in the Biological Sciences, or someone who expects to graduate in 1974, as experience is less important than the ability to fit into an existing team.

As part of that team, the person appointed would be required to carry out insecticide and nematocide screening tests to evaluate the effectiveness of novel compounds, and to assist in the culture of the insect colonies, including the

development of methods for new species.

We can offer a competitive starting salary and our other Company conditions of employment are amongst the market leaders.

For further details and an application form, please write, quoting reference 633/ to:

Personnel Department,
Fisons Limited—Agrochemical Division,
Chesterford Park Research Station,
Near Saffron Walden,
Essex, CB10 1XL.

(79)

Microbiologist

A vacancy has arisen within our expanding organisation at Havant, Hants, for a Microbiologist to join a small team involved in the microbiological quality control of pharmaceutical nutritional products.

The candidate should have a degree or equivalent qualifications in microbiology, age 25/45 and have at least two years experience.

A competitive salary will be paid depending upon age and experience.

The Company offers a non-contributory Pension and Life Assurance Scheme. Assistance with re-location expenses will be considered.

Please apply in writing to:—

Cameron Wolstenholme,
Director of Personnel & Industrial Relations,
John Wyeth & Brother Limited,
Huntercombe Lane South,
Taplow,
Maidenhead,
Berks, SL6 0PH.

Wyeth

(68)

A RESEARCH ASSISTANT is required by the Department of Virology for a project on respiratory viral infection. Salary scale £1,440 - £1,883 depending on experience. The post would be suitable for graduates in Microbiology or Biology wishing to gain experience in Virology and offers opportunities of obtaining higher degrees. For further information please contact Dr R. B. Heath, Virology Department, St. Bartholomew's Hospital, London EC1A 7BE (Tel 01-606 7777). Applications in writing to the Personnel Office quoting Ref: R/4577/N. (81)

ROTHAMSTED EXPERIMENTAL STATION

HARPENDEN, HERTS. AL5 2JQ

PHYSICAL or INORGANIC CHEMIST to assist in research on ion transformations in soils in relation to their classification and development, and to crop growth. Minimum qualifications: Degree, HNC or equivalent in Chemistry or Soil Science.

Interest in and knowledge of computer programming an advantage. Work includes the use of radiotracers.

Appointment in grade of Scientific Officer £1,435-£2,329 (scale under review). Superannuation with 51% non-pensionable allowance to offset contributions.

Applications giving full personal details, names of two referees, and quoting reference 2273 to the Secretary by 26th July, 1974. (86)

UNIVERSITY OF WESTERN AUSTRALIA Perth

ASSOCIATE PROFESSOR IN CLINICAL BIOCHEMISTRY (Royal Perth Hospital)

Applications are invited from experienced clinical biochemists with appropriate medical or science qualifications for the position of Associate Professor in Clinical Biochemistry on the staff of the University Department of Pathology. The appointee will be located at the Royal Perth Hospital and will be Head of the Hospital's Department of Biochemistry. He will participate in undergraduate and postgraduate teaching in Clinical Biochemistry and will undertake research and the supervision of M.Sc. and Ph.D. students. He will direct the Hospital Department of Biochemistry which has a well equipped service laboratory including multi-channel analysers and a computer.

The salary for an Associate Professor is \$A16,389 p.a. and a medically qualified appointee would also be entitled to a differential of \$A3,000 p.a. for clinical responsibilities. Benefits include superannuation similar to F.S.S.U., fares to Perth for appointee and dependent family, removal allowance, study leave and long service leave and housing loan scheme. Applications in duplicate stating full personal particulars, qualifications and experience should reach the Staffing Officer, University of Western Australia, Nedlands, Western Australia, 6009, by 3 August 1974. Candidates should request three referees to write immediately to the Staffing Officer.

Conditions of Appointment, application procedure and further details are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. (75)

JUNIOR TOXICOLOGIST

We shall shortly require an additional graduate to assist the Senior Toxicologist. The work will involve carrying out a wide range of toxicity tests in various subjects. The person appointed will have a degree in Pharmacology, Veterinary Medicine, or other biological science. Experience in toxicology, though desirable, is not essential. Reference No. 0316.

TERATOLOGIST

A vacancy occurs for a teratologist to carry out evaluations of drugs and environmental chemicals in various subjects. The person appointed will be aged 22-30 years and will be either an experienced technician in the field, or a graduate seeking to specialise in teratology. Suitable training will be given where necessary. Reference No. 0924.

CYTOGENETICIST

We have a vacancy for a cytogeneticist to carry out evaluation of drugs and environmental chemicals in mammalian cells for mutagenic activity. The person appointed is likely to have several years experience in this field. Reference No. 0923.

Please write for application form to:—

Mrs. M. Moul,
Inveresk Research International,
Inveresk Gate,
Musselburgh EH21 70B,

quoting Reference No.

(83)

AGRICULTURAL RESEARCH COUNCIL

UNIT OF DEVELOPMENTAL BOTANY

Applications are invited for a three year temporary appointment as a **SCIENTIFIC OFFICER** at the Agricultural Research Council's Unit of Developmental Botany. The successful candidate would be engaged in a supporting role in a small team engaged in a study of plant nucleic acids.

Applicants should have an honours degree in a biological subject, preferably Biochemistry, and be prepared to work closely with the team leaders. Starting salary, in the range £1,707 to £2,329 p.a., will be dependant upon qualifications and experience. Superannuation with an allowance to offset personal contributions.

Apply giving full details of qualifications and experience to the Secretary, Unit of Developmental Botany, 181A Huntingdon Road, Cambridge CB8 0DY. (63)

UNIVERSITY OF READING DEPARTMENT OF MICROBIOLOGY RESEARCH DEMONSTRATOR

An unexpected vacancy has occurred for a Research Demonstrator in the Department of Microbiology, commencing October 1, 1974. Applicants should have qualifications in microbiology, bacteriology, biochemistry or related subjects and have a special interest in the physiology and biochemistry of micro-organisms. Applicants should expect to demonstrate in practical classes up to 10 hours per week during term and to engage in research for a higher degree (M.Phil., Ph.D.). Salary scale £1,047 by £51 to £1,149 p.a. (under review). Further particulars from Dr L. J. Zatman, Department of Microbiology, University of Reading, London Road, Reading RG1 2AQ. (Ref. T.N. 44). (96)

THE CAMPDEN FOOD PRESERVATION RESEARCH ASSOCIATION

invites applications for the following post:

GRADUATE ANALYTICAL CHEMIST

with special responsibility for development of automated techniques. Ability to undertake committee work, prepare and present reports will be required. Knowledge of statistical techniques regarded as essential qualification for post.

Posts are graded on Research Officer salary scale. For further details write to: The Director, Campden Food Preservation R.A., Chipping Campden, Gloucestershire GL55 6LD. (93)

POSTDOCTORATE FELLOW IN IMMUNOGENETICS

Biochemist/Immunochemist with Ph.D. degree needed to work on the genetics of man's immune response toward limiting doses of naturally inhaled protein antigens (highly purified components of pollens, etc.). Opportunity to join a group which has had 3 years experience in this new research area. Excellent facilities and stimulating environment. Candidate must have a sound background in protein purification and characterisation. Experience in radioimmunoassay and leukocyte culture techniques advantageous. Demonstrated creativity in previous research essential. Send detailed curriculum vitae, list of publications and names of two referees to: Dr David G. Marsh, Johns Hopkins University School of Medicine at Good Samaritan Hospital, 5601 Loch Raven Boulevard, Baltimore, Maryland 21239.

Equal Employment Opportunity Employer M/F. (92)

UNIVERSITY OF LIVERPOOL DEPARTMENT OF BOTANY

Applications are invited for the following posts to commence work on September 2, 1974:—

1. **TECHNICIAN** to work in the microbiological laboratories and to help in the preparation of materials for culture of bacteria and fungi for both teaching and research. Some experience of handling microbes is essential. Initial salary within a range up to £1,794 per annum (plus threshold payments).
2. **TECHNICIAN** to help with teaching and research in ecology. An interest in both field work and chemical analytical techniques would be an advantage. Initial salary within a range up to £1,920 per annum (plus threshold payments).

Candidates for both these posts should possess at least Part I C. & G. or O.N.C. and preferably H.N.C. Application forms which should be returned as soon as possible may be obtained from the Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote ref RV/N/276117. (103)

NATURE CONSERVANCY COUNCIL SCIENTIFIC OFFICERS/ HIGHER SCIENTIFIC OFFICERS

Salary Range £1435-£2854

Applications are invited for the following three Assistant Regional Officer posts:

South Wales: The ARO will in the first instance be based at Cardiff. He will be responsible to the Regional Officer for work in that part of South Wales covered by the counties of Gwent and South and Mid Glamorgan. The area includes countryside of considerable interest to nature conservation but special emphasis will be required on the Council's activities in the urban/industrial districts.

Hebrides: Based initially in or near Portree in Skye, the ARO will be responsible to the Regional Officer for a wide range of conservation duties in Lewis, Harris, the Uists and in the Smaller Isles of the Outer Hebrides. He will be closely concerned with the management of the National Nature Reserves at North Rona and Sula Sgeir, St Kilda, the Monach Isles and Loch Druidibeg and the preparation of plans for these and other areas.

South Strathclyde: Based on proposed new Regional Headquarters near Glasgow, the ARO will be responsible to the Regional Officer for a wide range of conservation duties in the south Strathclyde area—excluding Argyll. He will be closely concerned with the management of the Loch Lomond National Nature Reserve and the preparation of plans for this and other areas.

Assistant Regional Officer duties include the survey and monitoring of wildlife resources, conservation of important nature conservation sites, and providing advice to a wide range of organisations. They will be expected to collaborate with Local Authorities and other official bodies, research and teaching establishments and Voluntary Conservation Organisations.

Candidates should normally be under 30 years of age with a degree (or equivalent) in an appropriate scientific subject. A current driving licence is essential.

Starting salary according to qualifications and experience.

Application forms and further particulars are available from Establishments (S) Nature Conservancy Council, 19 Belgrave Square, London SW1X 8PY. Please quote reference number E2/01/16.

Closing date for completed application forms: August 5, 1974. (85)

Overseas Development Administration Tropical Products Institute, London

Vegetable Oil Technologist

■ Research and advisory work on the processing of fats, oilseeds and edible nuts in order to assist developing countries to improve and utilise these resources ■ Considerable amount of field work overseas.

- ☐ 1st/2nd hons degree or equivalent in chemistry or biochemistry
- ☐ Experience of oilseed technology and of working in tropics an advantage
- ☐ Age under 32
- ☐ Appointment as Senior Scientific Officer (£3026-£4123 under review, plus threshold payments)
- ☐ Ref: SA/26/JD.
- ☐ Application forms (to be returned by 26 July 1974), from Miss C A Hall, Tropical Products Institute, 127 Clerkenwell Road, London EC1R 5DB.

**Science
group
CIVIL SERVICE**

North Western Regional Health Authority

Regional Administrative Scientific Officer

Owing to the impending retirement of the present incumbent, applications are invited for the post of Regional Administrative Scientific Officer at a salary of £5,409 rising to £6,648 per annum (subject to revision).

The successful applicant, who will be accountable to the Regional Medical Officer, should have appropriate professional qualifications in medicine or the sciences and should possess a broadly based scientific background.

This is a large region with three teaching hospitals and the Regional Administrative Scientific Officer must have the ability to plan, co-ordinate and advise on the development of National Health Service scientific services over the whole field of research, training, manpower, equipment, building design and service planning at regional level.

Further particulars and application forms to be returned by July 20, 1974, are available from the Regional Administrator, North Western Regional Health Authority, Gateway House, Piccadilly South, Manchester M60 7LP. Please quote reference No. 862.

(110)

CHIEF TECHNICIAN

At Ewell County Technical College, in the Biological Sciences Department.

To be responsible for organising the technical services, supervising technical staff and controlling the maintenance of modern equipment.

Applicants should have relevant experience and possess qualifications suitable for this important post.

36 hour week; 18 days holiday; staff restaurant and car park.

Salary: £2,031 to £2,340 according to age, qualifications and experience (currently under review).

Application form from Acting Chief Administrative Officer, Ewell County Technical College, Reigate Road, Ewell, Epsom, Surrey. Tel: 01-394 1731 (or 24 hour answering service). Please quote ref: CAO/E18/CTBS.

(145)

SURREY
COUNTY COUNCIL

RESEARCH SCIENTISTS CAN YOUR CAREER MAKE THE GRADE?

At Metal Box it will, because much of our success in providing the most profitable packaging for our customers' goods can be attributed to our Research Department. We are one of the largest packaging companies in the world supplying a comprehensive international service through subsidiary and associate companies.

We now require graduates to embark on a satisfying and challenging career in our Corporate Research and Developing Department. The work covers two different aspects of research—making innovative contributions to the Company's product range and solving problems arising in the manufacture and use of current packaging systems.

We are looking for men or women, who have first or higher degrees and are interested in Materials Science with particular reference to Polymers, Physics, Physical Chemistry and Metallurgy. The posts would ideally be suitable for either the recently qualified or for people with some post-graduate experience.

If you're looking for a really interesting career in a well-established organisation, please apply to: The Personnel Manager, **THE METAL BOX COMPANY LIMITED**, Corporate Research Department, Twyford Abbey Road, London, N.W.10.

(97)

UNIVERSITY OF IBADAN VACANCIES

Applications are invited from suitably qualified persons for the following posts:

DEPARTMENT OF BOTANY (JOS CAMPUS)

- (a) Senior Lecturer.
- (b) Lecturers.
- (c) Assistant Lecturer.

Applicants for Senior Lecturer should possess a doctorate degree and should have had extensive University teaching experience. The applicant will be responsible for the organising of Botany teaching at the Jos Campus.

Applicants for Lecturers should possess research experience and a good honours degree in Botany. University teaching experience will be an advantage.

Applicants for Assistant Lectureship should possess good honours degree in Botany.

DEPARTMENT OF ZOOLOGY (JOS CAMPUS)

- (a) Lecturers with interest in Invertebrate Zoology, Ecology, Genetics or Physiology.
- (b) Lecturer in Vertebrate Zoology.

An applicant should have a good Honours degree and a research degree in Zoology. University teaching experience will be an advantage.

DEPARTMENT OF PHYSICS (JOS CAMPUS)

Senior Lecturer/Lecturer/Assistant Lecturer.

Interest in Geomagnetism, Ionospheric Physics, Solid Earth Physics, Atmospheric Physics and Applied Geophysics as well as Solid State Physics (Theoretical or Experimental) will be of advantage.

Conditions of Service

Appointments are to commence as soon as possible, and successful candidates will be on probation for the first three years, but their appointments will be confirmed to retiring age thereafter if their services were considered satisfactory. Passages are paid for family on appointment, approved overseas leave and terminations where applicable. F.S.S.U./N.U.J.S.S. Children's and car allowances. Part-furnished accommodation or housing allowance is provided.

Method of Application

Detailed application (4 copies) stating age, full qualifications, experience, and naming three referees by July 31, 1974, to the Registrar, University of Ibadan, Ibadan, Nigeria, from whom further particulars may be obtained.

Salary Scales:

Senior Lecturer—N£5,030 by N£150 to N£5,480 by N£270 to N£5,750.

Lecturer—N£2,760 by N£150 to N£3,660/ N£3,810 by N£150 to N£4,260 by N£270 to N£4,530 by N£150 to N£4,830.

Assistant Lecturer—N£2,140 by N£100 to N£2,240 by N£220 to N£2,460 by N£100 to N£2,660 (if holding a higher degree N£2,460 by N£100 to N£2,660).

(77)

**UNIVERSITY COLLEGE LONDON
DEPARTMENT OF GEOLOGY
HYDROGEOLOGIST**

An appointment in the grade of DEMONSTRATOR will be made from October 1, 1974, to assist with the postgraduate training course in Hydrogeology and to work with Mr. G. P. Jones in one of the fields of research with which the Department is currently engaged.

Applicants should preferably have had some experience or qualification in Hydrogeology or Hydrology, and an interest in teaching and research. The Demonstrator may register for a higher degree. Salary range £1,494 to £1,743. Appointment will be for two years in the first instance.

Applications, together with names and addresses of two referees, as soon as possible to Assistant Secretary (Personnel) (N), University College, London, Gower Street, LONDON WC1E 6BT. (101)

**THE POLYTECHNIC
OF CENTRAL LONDON
SCHOOL OF ENGINEERING AND SCIENCE
LIFE SCIENCES**

RESEARCH ASSISTANT
£1,427 to £1,537

Applications are invited from good Honours graduates in Biology for a Research Assistantship tenable from September 1, 1974. The successful candidate will join the Pollution Research Group and will investigate the effects of pollutants from motorways on aquatic ecosystems. It may be possible for the successful candidate to register for a higher degree.

Details and application form from The Establishment Officer, PCL, 309 Regent Street, London W1R 8AL. 01-580 2020 Ext 212. (113)

**ST. GEORGE'S HOSPITAL
MEDICAL SCHOOL
HYDE PARK CORNER, LONDON SW1**

The Department of Medical Microbiology has a vacancy for an ELECTRON MICROSCOPE TECHNICIAN. The work involves the development of diagnostic methods in virus infections and research topics related to virology and to molecular genetics. Arrangements can be made for training in electron microscopy and related techniques. Starting salary in the range of £1,825 to £2,095 (including London Allowance). Application giving curriculum vitae to Professor H. Stern, Department of Virology, St. George's Hospital Medical School, Hyde Park Corner, London SW1. (144)

**AGRICULTURAL RESEARCH
COUNCIL**

**INSTITUTE OF ANIMAL PHYSIOLOGY
BARRAHAM, CAMBRIDGE CB2 4AT**

TWO RESEARCH POSTS are available for one year in the first instance at postgraduate or post-doctoral level. The work concerns the hormone activity of early embryonic tissue in relation to the establishment of pregnancy. Applications are invited from a candidate qualified to study the ontogeny of hormone activity in tissue culture and from a biochemist to investigate protein synthesis. The salary (scale currently under review) will be £1,435 to £2,329 p.a. according to qualifications and experience. Superannuation under FSSU with a non-pensionable allowance to offset contributions. Applications with full details and names of referees to the Secretary of the Institute, quoting reference P.H.4. (105)

**UNIVERSITY OF MALAYA
FACULTY OF SCIENCE
CHAIR OF ZOOLOGY**

Applications are invited for appointment to the Chair of Zoology in the Faculty of Science. Candidates should have high academic qualifications and wide experience in teaching and research at University level. Administrative experience would be an advantage. Subject to academic suitability and experience, preference will be given to candidates who are proficient in Bahasa Malaysia (Malay) but this requirement is not applicable to overseas staff. If selected, overseas staff may be offered a short-term contract subject to the possibility of renewal by mutual agreement.

Salary scale (approx. stg. equiv.): There is a range of basic salaries, to a point on which a Professor is appointed, depending on his qualifications and experience. These are £2,919, £3,032, £3,146, £3,259, £3,373, £3,486, £3,600, £3,713. In addition the following allowances are payable: Variable Allowance £243 min. £649 max. p.a. calculated at 35% of basic salary. Supplementary Housing Allowance £503 p.a., and medical benefits.

Further particulars and application forms are obtainable from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

The closing date for the receipt of applications is August 6, 1974. (106)

HEAD OF TISSUE CULTURE

£3,000 p.a. plus Pension

Applicant should have a sound theoretical and practical appreciation of the problems of tissue and organ culture based on several years postgraduate experience and an interest in toxicology and carcinogenicity studies.

This is a rapidly expanding contract research company located in modern, well equipped laboratories in a rural setting within 40 minutes of London. Please telephone Stock 840101 for further information or send full career details in strictest confidence to the director:

LIFE SCIENCE RESEARCH

Stock, Essex CM4 9PE, England

(111)

INFORMATION SCIENTIST

Borax Consolidated Limited, an international company within the RTZ Group, requires an Information Scientist for the Information Department at its Research Centre in Chessington, Surrey.

The information team is responsible for providing the Borax Companies throughout the world with technical, patents, and commercial information.

Candidates should have a degree (or equivalent qualification) in chemistry or a related field. Previous experience in information work is desirable and fluent reading ability in one or more modern languages will be a distinct advantage.

Every opportunity will be given to the successful candidate for fullest utilisation of ability and initiative.

The post offers an attractive starting salary and excellent fringe benefits including non-contributory pension and life insurance schemes.

Please write giving a brief outline of your career to:— The Personnel Manager, Borax Consolidated Limited, Borax House, Carlisle Place, London SW1P 1HT. (98)

**UNIVERSITY OF STRATHCLYDE
DEPARTMENT OF PHARMACEUTICAL TECHNOLOGY
RESEARCH FELLOW (CELL BIOLOGIST)**

Applications are invited for the post of Research Fellow (Postdoctoral preferred) for two years in the first instance to work on drug effects on cultured human cells.

Salary within the range £2,118 to £2,412 plus FSSU.

Applications (quoting R24/74) with curriculum vitae and names of two referees should be addressed, as soon as possible, to Dr Mary Dawson, Department of Pharmaceutical Technology, University of Strathclyde, Royal College, 204 George Street, Glasgow G1 1XW, from whom further particulars may be obtained (Tel. 041 552 4400 ext 2113). (112)

UNIVERSITY OF RIYADH MEDICAL SCHOOL—SAUDI ARABIA

(In association with the University of London)

Applications are invited from FEMALE honours graduates preferably holding a doctorate and with teaching experience for the following posts:—

SENIOR LECTURER/LECTURER IN PHYSICS SENIOR LECTURER/LECTURER IN CHEMISTRY SENIOR LECTURER/LECTURER IN BIOLOGY

Since the opening of the Medical School in 1969 only male staff and students have been accepted. In the 1974-75 academic year, a start is to be made in the medical training of women. Ten premedical female students are to be accepted at the School in the first instance. Appointees will be responsible for a teaching programme for these students according to an agreed syllabus which has already been prepared. The teaching load will be shared by all lecturers who will also be jointly responsible for examining the students' progressive attainment and for organising the practical work of the course.

The basic premedical sciences course will last for approximately 1½ academic years. In the premedical course the female students will be taught in segregated classes, but in the preclinical and clinical years, classes will be coeducational.

Salary Scales:—Senior Lecturer Saudi Ryals 4,500 x 200—5,700 per month. Lecturer Saudi Ryals 3,500 x 200—4,700 per month. Housing allowance of SR10,000 p.a. for Senior Lecturers and SR 8,000 p.a. for Lecturers. (Present rate of exchange is £1 sterling = 8.5 Saudi Ryals). In Saudi Arabia currencies are freely convertible and transferable. Appointments are for one year or longer; renewable.

Detailed applications (three copies) with the names of three referees should be addressed to the Inter-University Council for Higher Education Overseas, 90-91 Tottenham Court Road, London W1P 0DT, not later than July 26, 1974. (99)

UNIVERSITY OF THE WEST INDIES JAMAICA

Applications are invited for the post of LECTURER/ASSISTANT LECTURER IN CHEMISTRY

Appointee should have an interest in Organic Chemistry. Salary scale: Lecturer J\$6,168 to \$9,768 p.a., Assistant Lecturer J\$5,006 to \$5,486 p.a. (£1 sterling = J\$2.20). FSSU. Unfurnished accommodation will be let by the University at a rental of 10% of salary. Family passages; triennial study leave. Detailed applications (6 copies) including a curriculum vitae and naming 3 referees should be sent as soon as possible to the Registrar, University of the West Indies, Mona, Kingston 7, Jamaica. Further particulars are available from the same source and should be obtained before an application is made. (100)

UNIVERSITY OF AUCKLAND NEW ZEALAND

SENIOR LECTURESHIP/ LECTURESHIP IN GEOGRAPHY

Applications are invited for the above-mentioned post. Preference will be given to candidates with qualifications in the Geography of East Asia and in either Climatology or the Geography of Transport. Applications will also be considered from persons with systematic specialist interests in other branches of physical or cultural geography.

Salary scales: Commencing salary within the appropriate scale will be determined in accordance with qualifications and experience. Senior Lecturer: NZ\$8,713 to \$10,232 p.a.; in exceptional cases the NZ\$8 may extend this scale up to \$11,139. Lecturer NZ\$6,753 to \$8,568 p.a. An allowance is made towards travel and removal expenses and superannuation is available on an FSSU basis.

Further particulars, conditions of appointment and application procedure obtainable from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close on July 31, 1974. (108)

UNIVERSITY OF SYDNEY DIRECTOR OF THE SAMPLE SURVEY CENTRE

Applications are invited from persons qualified and experienced in the theory and practice of sample surveys for the position of Director of the Sample Survey Centre. The appointee to this position will have professorial status.

Salary rate: \$A19,614 p.a.

A statement of Conditions of Appointment and Information for Candidates may be obtained either from Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar, University of Sydney, N.S.W. 2006, Australia. Applications close on August 15, 1974. (109)

UNIVERSITY OF SYDNEY MARINE STUDIES CENTRE

FIXED-TERM LECTURESHIP IN PHYSICAL OR CHEMICAL OCEANOGRAPHY

Applications from suitably qualified scientists are invited for a Fixed-term Lectureship in Physical or Chemical Oceanography in the Marine Studies Centre. The appointee will be expected to develop courses in the principles of physical and chemical oceanography to third year students in the Faculty of Science with a background in the biological or earth sciences.

The appointment will commence as early as possible in 1975 and will terminate on December 31, 1975, in the first instance.

Salary range: \$A9,002 to \$12,352 p.a.

Applications including curriculum vitae, list of publications and names of three referees, by July 26, 1974, to the Registrar, University of Sydney, N.S.W. 2006, Australia, from whom further information is available. (107)

TECHNICIAN

required to assist in research on cancer and immunology in Dept. of Experimental Pathology. Previous laboratory experience required. Salary depending on qualifications and experience. Apply: The Secretary, St. Mary's Hospital Medical School, Paddington, London W2 1PG, quoting Ref. EP 2. (148)

UNIVERSITY OF READING DEPARTMENT OF CHEMISTRY RESEARCH DEMONSTRATORS

required in inorganic and physical chemistry from October 1, 1974, for three year appointment. Candidates should have a good Honours Degree in Chemistry, or equivalent qualifications. Demonstrators help supervise practical classes and undertake research leading to a higher degree (M.Phil or Ph.D.). Salary in the scale £1,046 x 51 to £1,149 p.a. (Under review). Apply to Professor G. W. A. Fowles, Department of Chemistry, University of Reading, Whiteknights, Reading, from whom further information about research topics can be obtained. (Ref: T 52.) (147)

LIVERPOOL POLYTECHNIC SCHOOL OF PHARMACY SCIENTIFIC ASSISTANT IN MEDICAL CHEMISTRY

Applications are invited for a scientist experienced in organic methodology to work on a project in the field of narcotic analgesics approved by MRC. Salary £2,100 for a minimum of 3 years which may be supplemented by teaching duties.

Enquiries and applications to: Dr. A. F. Casy, School of Pharmacy, Liverpool Polytechnic, Byrom Street, Liverpool L3 3AF. (146)

RESEARCH STUDENTSHIPS

Applications are invited for two three-year Research Studentships, tenable from October 1, 1974, at the M.R.C. Dunn Nutritional Laboratory, Cambridge, in the following areas:

(1) The relationship between protein metabolism and hormonal status in animals subjected to protein-energy malnutrition.

(2) The biochemical effects of riboflavin deficiency in an experimental animal, to relate the known parameters of subclinical riboflavin deficiency with biochemical lesions which may have pathological consequences. These studies will form part of a new programme, the aim of which is to examine various aspects of human nutritional status in relation to the water-soluble vitamins.

Applicants should have, or be expecting this summer, a first or upper second class honours degree, preferably in Biochemistry or Nutritional Science, and should send their curriculum vitae and names of two referees for (1) to Dr P. G. Lunn and (2) to Dr C. J. Bates, at the Dunn Nutritional Laboratory, Milton Road, Cambridge CB4 1XJ, not later than June 30, 1974. (4)

KING'S COLLEGE, CAMBRIDGE FELLOWSHIP IN APPLIED PROBABILITY THEORY IN RELATION TO POPULATION BIOLOGY

Applications are invited for Fellowships in the above field, including population and human genetics, ecology, evolutionary theory, demography and stochastic diffusion processes to be held (from October 1975 or by arrangement) in the King's College Research Centre where computing facilities are available. Senior (age limit of 32) and Junior (age limit of 28 years and not more than about 3 years research experience) fellowships are available, together with an unrestricted fellowship which could be held by a senior worker on sabbatical leave. Maximum tenure, 4 years. Closing dates: **October 1, 1974**, for seniors and open; **November 15, 1974**, for juniors.

Salary: This is based on age and linked to the University lecturer scale. For an unmarried Fellow who is provided with free-accommodation in the College it ranges at present from about £1,500 at age 24 or below to £3,450 at age 36. Married Fellows receive £500 more, £625 if they have a dependent child or children.

Details of accommodation, research facilities, etc., from: The Convener, King's College Research Centre, King's College, Cambridge CB2 1ST, England. (11)

UNIVERSITY OF GLASGOW DEPARTMENT OF CELL BIOLOGY RESEARCH STUDENTSHIP

Applications are invited for a research studentship to work on the role of proteins in the structure and organisation of cell membranes. Candidates should expect to have a 1st or upper second class honours degree.

Applications, giving age, experience, and the names of two referees, to Dr A. J. Lawrence, Department of Cell Biology, University of Glasgow, Glasgow G11 6NU.

In reply please quote Ref. No. 3498M. (17)

UNIVERSITY OF GLASGOW

Applications are invited for a research studentship to work on aspects of bacterial electron transport or nitrogen fixation. Candidates should have, or expect to obtain this year, a first or upper second class Honours degree in an appropriate subject, and the successful applicant will be expected to register for a Ph.D.

Applications stating age, qualifications, experience, and the names of two academic referees, should be sent as soon as possible to Dr R. M. Daniel, Department of Cell Biology, University of Glasgow, Glasgow G11 6NU.

In reply please quote Ref. No. 3491M (18)

UNIVERSITY OF KENT AT CANTERBURY Studentships in Chemistry

Applications are invited for the following three SRC (C.A.S.E.) Studentships.

(1) To work with Drs A. V. Chadwick and J. D. Wright, in collaboration with the Safety in Mines Research Establishment (Dept. of Energy), on the effect of gases on electrical properties of semi-conducting molecular crystals.

(2) and (3) To work with Prof E. F. Caldin and Dr B. H. Robinson, in collaboration with two major oil company research establishments, on the properties and applications of micelles formed in non-aqueous solvents, using fast-reaction techniques.

Applicants should have good Honours degrees in Chemistry, Chemical Physics, Physics (1) or Biophysics (2) and (3).

Applications should be made to the Assistant Registrar, Chemical Laboratory, The University, Canterbury, Kent, CT2 7NH., from whom further details may be obtained. Closing date July 26, 1974. Please quote ref. PG 7/74. (35)

FELLOWSHIPS AND STUDENTSHIPS

LEUKAEMIA RESEARCH FUND RESEARCH FELLOWSHIPS

The Leukaemia Research Fund invites applications by August 2, 1974 from suitably qualified graduates, medical or non-medical, for a Fellowship in leukaemia research in a field of special interest to the Fund, tenable in France for one year in association with I.N.S.E.R.M. A second year's support in Britain is also offered. The salary in France will be up to a maximum of 61,500 French francs per annum. Applications, with the names of two referees, to the Secretary, Medical Advisory Panel, Leukaemia Research Fund, 61 Great Ormond Street, London WC1N 3JJ. (88)

WATER POLLUTION STUDIES

Imperial College
POSTGRADUATE
STUDENTSHIP

Applications are invited from suitably qualified graduates in Biological Sciences, for an S.R.C. Postgraduate Studentship tenable in the Public Health Engineering Laboratory.

The Research project which the successful candidate will undertake comprises part of a programme of bacteriological studies intended to obtain fundamental information about the ecology of the bacterial populations involved in sewage treatment.

Applications, enclosing a curriculum vitae, should be sent to:

**Dr R. Perry,
Public Health Engineering,
Imperial College,
London, SW7.**

Telephone: 01-589 5111 Ext. 1362.

(44)

DEPARTMENT OF PHYSICS University of Leicester RESEARCH STUDENTSHIPS IN X-RAY ASTRONOMY

Two S.R.C. Studentships, for research leading to the Ph.D. degree, are available from October 1974 in the X-ray Astronomy Group. Research opportunities are expected to exist in the following areas:

- analysis and interpretation of data from the Group's sky survey and spectrometer-polarimeter experiments on the UK-5 X-ray satellite, due for launch in September;
- experimental work on cosmic X-ray rocket payloads concerned with the mapping and spectroscopy of galactic supernovae and close binary sources;
- experimental and theoretical study of the X-ray spectrum and structure of solar coronal active regions and flares;
- laboratory development of imaging devices and readout systems appropriate to future X-ray astronomy missions.

Applications are invited from students in Physics, Electrical Engineering or Mathematics who expect to obtain a good Honours Degree this summer and should be addressed to Professor K. A. Pounds at the above address. (16)

RESEARCH STUDENTSHIP

available for a graduate (Class I or 2i) in Biochemistry to participate in a programme of research on haemoglobin and other blood proteins of lower Primates. Apply to Professor N. A. Barnicot, Dept. of Anthropology, University College London, Gower Street, London WC1E 6BT. (40)

UNIVERSITY OF BATH SCHOOL OF BIOLOGICAL SCIENCES Studentship

Applications are invited from biochemists and microbiologists with a first or upper second degree for appointment to an SRC studentship for work on yeast membranes and vesicles. Further information can be obtained from Professor A. H. Rose, School of Biological Sciences, University of Bath, Claverton Down, Bath, BA2 7AY. (34)

THE UNIVERSITY OF MANCHESTER INSTITUTE OF SCIENCE AND TECHNOLOGY Department of Biochemistry

A Science Research Council postgraduate research studentship, is available either for work in an existing group on the synthesis and regulation of pyruvate carboxylase in thermophilic bacteria, or on some related topic in microbial biochemistry. Applications with the names of two referees should be sent to Professor A. A. Eddy, Department of Biochemistry, U.M.I.S.T., Manchester, M60 1QD. (67)

The Jack Charrington Memorial Fellowship 1974/75

Applications are invited for the award of The Jack Charrington Memorial Fellowship from British Subjects, normally resident in the U.K., who are associated with the Coal Industry or Coal Trades.

The object of the fellowship is to encourage the study of new developments associated with the coal industry or coal trades in other countries with special reference to the application of such developments in the United Kingdom. Applicants must nominate the new development and country in which they propose to carry out the study.

The holder of the fellowship will be granted a stipend of up to £5,000 for a year's tenure or proportionately less for a shorter study. In addition travelling expenses will be met. Part of the tenure will be spent in writing a report.

Applications with full curriculum vitae, a synopsis of the new development and country in which they propose to undertake the study should be submitted by July 31, 1974, to the Secretary, The British Coal Utilisation Research Association Limited, Dept. N.I., C/O National Coal Board, Coal Research Establishment, Stoke Orchard, Nr. Cheltenham, Glos. GL52 4RZ. (33)

Research Studentship

at the Institute of Marine Biochemistry,
Aberdeen

Applications are invited from graduates with a first of upper-second class Honours degree in biochemistry for a research studentship (3 years) provided by the Natural Environment Research Council. The work will be on the biochemistry of cellular and humoral immune mechanisms in marine invertebrates and will probably centre around the nature and function of constitutive glycoproteins. Some collaboration with bacteriologists and virologists with marine interests is envisaged. The successful applicant will be expected to register as a PhD student with the University of Aberdeen and will receive a basic grant, currently £695 per annum, plus approved fees.

Applications to:

**Dr P. T. Grant,
Institute of Marine Biochemistry,
St Fittick's Road,
Aberdeen AB1 3RA.**

(46)

UNIVERSITY OF MANCHESTER DEPARTMENT OF CHEMISTRY POSTGRADUATE STUDENTSHIP

Applications are invited for an S.R.C.—C.A.S.E. studentship to work on the mechanism of chelation and demetallisation of metal complexes with Dr. J. A. Connor and in collaboration with Dr. R. Price of I.C.I. Organics Division. The project will involve both preparative organic and inorganic chemistry together with the application of physical methods of measurement in the elucidation of a problem which is of basic importance to transition metal chemistry and of significance to the dyestuffs and metallurgical industries. Applicants should write as soon as possible to Dr. J. A. Connor, Department of Chemistry, University of Manchester, Manchester M13 9PL. (54)

THE UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF ORGANIC CHEMISTRY

Applications are invited for a research studentship to work on chemical modifications of B-lactam antibiotics. The work is supported by a grant from Beecham Research Laboratories and the studentship (£695 p.a. plus fees) is for three years. The successful candidate, who must have a good Honours Degree in Chemistry or an equivalent qualification, will be expected to study for the Ph.D. Degree.

Applications, naming two referees, should be sent to Dr. R. P.J. Stoodley, Department of Organic Chemistry, The University, Newcastle upon Tyne NR1 7RU, as soon as possible. (57)

TEESSIDE POLYTECHNICS

Research Studentship

Science Research Council Studentships are available in the Polytechnic for research in topics selected from the following:

Scientific/Engineering Appraisal of the Problems of Sub-Standard Mine Waters
Synthesis of Novel Nitrogen-heterocyclic Compounds
Bio-chemical Engineering
Pollution Studies
Macroeconomics in Chemical Engineering XX
Microgeometry of Engineering Surfaces
Flow Measurement Using Correlation Techniques
Computer Animation of Non-Rigid Objects
Ironmaking in the Blast Furnace
Control and Instability of Fluid Distribution Systems
Algebraic Semigroups and mappings of S-sets

Candidates for these studentships should hold, or expect to be awarded, an upper second class honours degree in an appropriate branch of science or engineering, or an equivalent qualification.

Further details and application forms are available from the Staffing Section, Department N, Teesside Polytechnic, Borough Road, Middlesbrough, Teesside TS1 3BA and should be returned within 14 days. (38)

UNIVERSITY COLLEGE CARDIFF
C.A.S.E. STUDENTSHIPS

1. C.A.S.E. studentship tenable in the Department of Microbiology, to study the effect of Ozone on biorefractory organic materials in effluents.
2. Microbial Degradation of Petroleum Products. The disposal of petroleum products such as rolling and cutting oils can involve microbiological treatment. Formulations are complex and we need more information on the fate of the individual ingredients.

Candidates should possess a good degree in Microbiology or Biochemistry. Applications, together with the names and addresses of two referees, should be forwarded to Professor D. Hughes, Department of Microbiology, University College, P.O. Box 97, Cardiff CF1 1XP. Please quote ref. 0599. (28)

FELLOWSHIP IN SALMON
DISEASES

Applications are invited by the Atlantic Salmon Research Trust for a Research Fellow to be based at the Farran Laboratory of the Salmon Research Trust of Ireland, Newport, Co. Mayo, Ireland, in association with the Unit of Aquatic Pathobiology of the University of Stirling, with whom the successful candidate will be expected to register for a Ph.D. Application forms and conditions of service are available from the Director, Atlantic Salmon Research Trust Ltd., 29 South Street, Farnham, Surrey. Completed application forms to be received by July 31. (90)

ROYAL FREE HOSPITAL SCHOOL
OF MEDICINE
DEPARTMENT OF BIOLOGY
POSTDOCTORAL RESEARCH

Applications are invited from graduates in pharmacology or related subjects for a three-year research post at the postdoctoral level, supported by The Nuffield Foundation. The project concerns the rôle of genetic variation in the ability to metabolise foreign substances in the mouse. Starting date October or November 1974. Technical help will be available.

Salary £2,091 to £2,220 to £2,385 p.a. Plus F.S.S.U. Applications, with curriculum vitae and two referees, to Dr. I. E. Lush, Department of Biology, Royal Free Hospital School of Medicine, 8 Hunter Street, London WC1N 1BP. (94)

SCOTT POLAR
RESEARCH INSTITUTE
UNIVERSITY OF CAMBRIDGE
RESEARCH STUDENTSHIP

A research studentship of NERC which involves working for a Cambridge Ph.D. is offered for radio echo studies of polar ice sheets. Field work involves extensive sounding flights over Antarctica in Hercules aircraft from the USA. General and computer analyses of results and development of equipment is carried out in Cambridge. Requirements: II.1 degree in physics, geophysics, electronics or engineering. These could be concerned with electromagnetic propagation in or properties, flow, etc., of ice sheets or ice shelves, sub ice geology and/or associated geophysical problems.

Please contact Dr Robin, Director, SPRI, Cambridge CB2 1ER. Telephone 0223-66499 ext 400. (104)

RESEARCH
STUDENTSHIPS

Two Co-operative Awards in Science and Engineering, will be available from October 1974 for 3 years. Applications are invited from graduates with a good honours degree.

1. University of Bristol—Research Studentship in Biochemistry

Applicants should hold an honours degree or be about to complete an honours course in Biochemistry or Chemistry, to carry out research on protein chemistry of collagen with particular reference to the chemical nature of stability of the crosslinks stabilising the collagen fibres of various tissues used in gelatin manufacture. The project, which will be undertaken in collaboration with the Gelatine Division of the British Food Manufacturing Industries Research Association, will be supervised by Dr A. J. Bailey.

2. Meat Research Institute—Research Studentship

A good honours degree and background in physiology/biochemistry/pharmacology, would be advantageous to join a multidisciplinary research team concerned with the physiology of growth and development, examining lipid metabolism and the effects of lipolytic and autolipolytic agents in farm animals. The work is expected to form a basis of a PhD thesis registered at University of Bristol. It will be carried out in collaboration with May & Baker Ltd at their Veterinary Research Division at Ongar, Essex and supervised by Dr D. Lister.

Further particulars of award and allowances, together with a form of application from:

SECRETARY
MEAT RESEARCH
INSTITUTE
LANGFORD
BRISTOL, BS18 7DY

(19)

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF AERONAUTICS
AND ASTRONAUTICS
SPITFIRE MITCHELL MEMORIAL
STUDENTSHIP

Applications are invited from holders of good honours degrees in Engineering or Science, or Mathematics to engage in aimed research in a branch of Aeronautics and Astronautics in the spirit of the work of the aviation pioneer, R. J. Mitchell, in whose memory the Studentship is awarded.

The value of the Studentship, which is for two years and may be extended to a third year, will be not less than £700 per annum, exclusive of fees. Candidates must register for a higher degree. Closing date for applications 30th September 1974.

Further details and application form may be obtained from:- The Academic Registrar, The University, Southampton SO9 5NH. (56)

UNIVERSITY OF DUNDEE
DEPARTMENT OF BIOLOGICAL SCIENCES
Applications are invited from graduates with a final or upper second class honours degree in Microbiology or in Botany or Biochemistry with subsidiary Microbiology for a

NERC RESEARCH STUDENTSHIP

to be held for up to three years in the above Department for work under Dr. C. M. Brown on bacterial interactions in an estuarine environment.

Applications, naming two referees, should be sent to Dr. Brown at the Department of Biological Science, The University, DUNDEE DD1 4HN as soon as possible. (66)

UNIVERSITY OF BRISTOL
Department of Anatomy
POSTDOCTORAL RESEARCH
FELLOWSHIP

Applications are invited for a Postdoctorate Fellowship, sponsored by the Medical Research Council, to work in collaboration with Dr D. W. Lincoln and Dr Carol A. Mason on the electrophysiology of the neurosecretory nuclei of the rat hypothalamus, with a view to understanding the mechanisms that determine the pulsatile release of oxytocin in milk ejection and labour. Previous experience of intra- and extracellular recording from single neurones and the computerised analysis of this data would be useful, though not essential.

The appointment is for one year from September 1, 1974, renewable for two further years. Initial salary up to £2,247 p.a.

Applications giving details of age, qualifications and experience, together with the names of two referees, should be sent by July 20 to Dr D. W. Lincoln, Department of Anatomy, The Medical School, University of Bristol, Bristol BS8 1TD, from whom further particulars are available. (37)

LECTURES AND COURSES

FEBS Advanced Course No. 28

Rapid Reactions
in Biochemistry

Rome, October 21—26, 1974

This Advanced Course, for 20-25 participants, will consist of lectures and practical demonstrations on methods for studying rapid reactions, application to biochemical systems, and analysis of kinetic data.

The Course fee of about DM 300 will include accommodation and meals.

Applications should be sent as soon as possible to: FEBS Advanced Course, c/o Prof. E. Antonini, Istituto di Chimica Biologica, Città Universitaria, 00185 Roma, Italy, with a copy to Prof. M. Gruber, Biochemisch Laboratorium, Zernikelaan, Groningen, The Netherlands. (7)

Plymouth Polytechnic
PRACTICAL BIOLOGICAL
ELECTRON MICROSCOPY

Residential Course

September 9-14, 1974

Recent Sedimentary Carbonates

In Two parts by J. D. Milliman · G. Müller · U. Förstner

Part 1

J. D. Milliman Marine Carbonates

By **John D. Milliman**, Woods Hole Oceanographic Institution,
Woods Hole, MA 02543, USA

With 94 figures and 39 plates. XV, 375 pages. 1974

Cloth DM 66,—; US \$25.50 ISBN 3-540-06116-9

Prices are subject to change without notice

This is the first integrated discussion of the entire field of marine carbonates, their ecology, precipitation, petrography, composition, distribution and diagenesis. It deals with those carbonates which form and occur within the modern-day marine environment. The book is divided into four parts. Of particular significance in the first part is a discussion of the various petrographic and mineralogic techniques used in studying carbonates.

The major portion of the book attempts to synthesize the voluminous literature on the calcification, composition and petrography of various marine carbonate components. Growth rates, mineralogies, minor, and trace-element and stable-isotope distributions have been tabulated; the petrography is presented in both line drawings and photographic plates.

The environments and sediments of carbonate deposition are covered in the third part; it includes discussions of shelf and deep-sea carbonates, subjects rarely mentioned in other texts, but which were probably of extreme importance in ancient deposits.

The last part concerns the diagenetic alteration and cementation of carbonates in the ocean. Many of the data presented here are new or represents original tabulations of various marine cements and limestone types.

Collected Nature

These specially designed Binders make attractive space-saving files for your **Nature**. Bound in durable black imitation leather, lined with grey deer skin and beautifully labelled, each binder will hold up to eighteen copies of **Nature**. Two volumes of **Nature** can be preserved in a single binder, (three binders will hold the six volumes published annually) and there is a white space on the spine to enable you to mark each binder with your own reference to the issues it contains.

These binders are offered for sale singly for £1.85 or in packs of three for £5.00. Both prices include postage by surface mail and V.A.T. To order please complete the coupon below and return it with the appropriate remittance.

NATURE, Macmillan Journals Limited, Brunel Road, Basingstoke, Hampshire RG21 2XS.

Please send me:

1 NATURE BINDER (I enclose £1.85)

3 NATURE BINDERS (I enclose £5.00)

(Payment may be made in any currency at the current rate of exchange)
Prices applicable only to orders received before the 30th June 1975.
Orders can only be serviced if accompanied by remittance, cheques should be made payable to Macmillan Journals Limited.

High speed maths

How many times a day do you use an adding machine, slide rule or scribble calculations on paper? It's a slow old business. Slows down business too.

What you need are high speed fingertip maths as found in the new Tektronix 21 and 31 scientific programmable calculators.

Tektronix-calculator answers are more than instant! They are ready and waiting! Built into the calculator's mathematical logic. Even before you tap your problem in!

Easy-to-understand data feed-in keys labelled with familiar maths symbols and plain everyday English make these calculators amazingly easy to use. Fingertip operation of a data key is a complete mathematical function in key stroke form. It's that simple.

But don't be fooled by the deceptive simplicity of these calculators. Each packs calculating power so great, they solve problems formerly 'computer only'. And at far less cost!

What's more the 21 and 31 don't just solve problems. They learn them

from your simple key-English programming. Use the 21 and 31 for high speed complex-problem answers to different input variables. Save yourself valuable analytical thinking time. Decision-make with confidence.

With the silent thermal alphanumeric printer, the 31 will 'talk' to you. Give hard copy answers and instant programme advice. Tell you the how, where and what of data entry. Debug, edit and label programmes.

And talking about labels Tektronix is

a relatively new name in calculators. But we've been in electronics for 25 years. We're international precision electronic measurement specialists... with some of the best scientific minds in the world. So it was natural we conceived the 31... at *£1449 one of the most powerful problem-solving-per-£ calculators on the market... followed closely by its smaller brother the 21 at *£940.

Take a calculated step — fill in the coupon, or telephone for full details, and a demonstration now.

Please send details and arrange a demonstration

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.

- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).

- 'Matters arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. $\exp(a)$ is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of *Nature*. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in *Nature* (246, 238; 1973).

Secretion-dependent uptake of extracellular fluid by the rat neurohypophysis— <i>P. F. Baker, M. Ravazzola, F. Malaisse-Lagae and L. Orci</i>	155
Food vacuole membrane in nutrient uptake by <i>Tetrahymena</i> — <i>L. Rasmussen</i>	157
Aerosol particles on tobacco trichomes— <i>R. L. Fleischer and F. P. Parungo</i>	158
Phytochrome intermediates in freeze-dried tissue— <i>R. E. Kendrick</i>	159
Chemical and biological degradation of waste plastics— <i>B. S. Brown, J. Mills and J. M. Hulse</i>	161
Haidinger's brushes and predominant orientation of collagen in corneal stroma— <i>C. C. D. Shute</i>	163
The apparent heaviness of colours— <i>E. Pinkerton and N. K. Humphrey</i>	164
Male sterility induced in barley by photoperiod— <i>J. J. Batch and D. G. Morgan</i>	165
Fluidisation as a feeding mechanism by beach flies— <i>L. Cheng and R. A. Lewin</i>	167

BOOK REVIEWS

The Triumph of the Darwinian Method (M. T. Ghiselin)— <i>William B. Provine</i>	169

YOUR FUTURE IN ELECTRON OPTICS...

WILL YOU WANT YOUR LABORATORY TO BE UP-TO-DATE, WITH A MINIMUM OF INVESTMENT?

Of course you will. But, with advances in electron optics coming so often these days, keeping current without bending the budget isn't as easy as it used to be.

In theory, the secret lies in always having as much electron optical capability as you need... but never any more than you need. In finding a way to continuously match the job to be done with the instruments available. In building an ability in electron microscopy precisely suited to the requirements of today... yet fully adaptable to those of tomorrow.

Too much to expect? Not at all. In fact, whatever your needs... now or later... there's a Philips instrument for you now!

Do you want non-specialist operators to produce more really high-quality micrographs in less time? **The EM 201C**. Do you want to enjoy the benefits of SEM without the usual complications? **The PSEM 500**. Do you want to do X-ray micro-analysis on transmission specimens? **Try TEAM**. Do you want to experiment with STEM and SEM without buying a new instrument? **The EM 301 plus S(T)EM Unit**. Quantitative image analysis? **Quantimet**.

And this list is only part of Philips systems approach to the future. Read more about it in our brochure.

PHILIPS

Hedging & fence-sitting from the Think Tank

ONE of the prime skills of the politician is to find the right words to ensure that nothing is given away during debate. The academic politician, canniest of them all, is usually able to find the most eloquent way of keeping open all options, and even in response to the most mundane question will unearth a convoluted answer. "Will all the delegates be coming in to dinner?" the Master of a Cambridge college was asked recently. "Some . . . but perhaps by no means all" was his reply. The Think Tank's latest offering, *Energy Conservation* (HMSO, £1.00) is replete with such generalised High Table fence-sitting.

The Central Policy Review Staff (CPRS) set itself—at least nowhere is there any indication that the idea sprang from elsewhere—the task of producing a document for public discussion on how energy conservation might be achieved. A broad interpretation was put on the words 'energy conservation' and the CPRS included an analysis of methods of using replenishable forms of energy as a means of conserving fossil-fuel-generated energy. We reported last week the outlines of the report. What concerns us here is whether the CPRS does a good job when venturing into such fields and whether energy conservation is an appropriate matter for the CPRS to study in any case.

The most striking feature of the report to a scientist is the utter lack of any substantiating material for all that is said. In the report's 64 pages it roams widely over material as varied as domestic insulation and energy from sea waves. The authors (anonymous, of course) have clearly done a lot of reading and presumably have also been to see many of the scientists and technologists whose work forms the basis of the report's conclusions. Yet nowhere is there a single reference to published work, nor to a conversation with anyone. As a result it is extraordinarily difficult for this document to be a vehicle for public discussion. Beautifully manicured paragraphs that would have delighted Gowers for their style and clarity are no substitute for well documented arguments.

Consider, for instance, the Severn barrage scheme. It is described and dismissed in two paragraphs. "Significant environmental benefits are claimed by proponents [here follows a list of benefits] . . . They are not, however, easy to substantiate and would not appear to transform an apparently uneconomic project into an economic one . . . The long term ecological effects are very uncertain." This may be an elegant way of covering a lot of ground but it leaves the reader with too many unanswered questions—who are the proponents, why are the benefits not easy to substantiate, who is concerned with long term ecology? Or again in discussing energy storage schemes, " . . . nevertheless, the widening

differential between nuclear and fossil fuel costs in favour of the former may prove sufficient to make at least some of these schemes economic." Some, but perhaps by no means all.

The central question, however, is whether the CPRS should be doing this sort of study at all. There are various spurious arguments that can be raised against its involvement, such as that the staff cannot possibly be technically qualified or that the subject is more properly a departmental matter. If a Think Tank is a good thing, and we believe it to be so, then it must certainly be allowed to do what it wants and to risk offending the specialist departments. What it must not do, for its own sake, let alone that of taxpayers, is to bite off more than it can chew. This it has palpably done in this case.

Not only is the subject of energy conservation colossal in extent, but the CPRS has expanded it even more by discussing the economy of the inexhaustible resources. With such a wide field it is almost inevitable that there will be no incisive thinking, since the staff, desiring to be comprehensive, can have had little time to develop expertise in individual areas. The overall impression that the report gives is of diligent reading—and there has been ample material to read in the last year—but no very profound thinking. The document bears no marks of being the subject of intensive discussions amongst the staff; indeed it seems instead the sort of thing that an academic might produce during a sabbatical year. This, surely, is not what the Think Tank should be all about. If, in the future, the CPRS does not want to get a reputation amongst scientists for vapid thinking it will have to concentrate its attention much more.

100 years ago

If anyone wants to see how lamentable is the absence of practical work in the examination system of the University of London, let him get "Questions in Chemistry and Natural Philosophy given at the Matriculation Examination of the University of London from the year 1864 to June 1873, classified according to the syllabus of subjects," by C. J. Woodward, B.Sc. (Simpkin, Marshall, & Co.) We say nothing against the book itself, which is a creditable compilation of its kind, but the system capable of giving birth to such a text-book must be an unmitigated encouragement to "Cram."

From *Nature*, 10, 215, July 16, 1874.

Gamma-ray astronomy: the last observational frontier

ON June 10, 11 and 12 a symposium on "The Context and Status of Gamma Ray Astronomy" was held at the ESRIN laboratory in Frascati. The rationale behind such a symposium under the ESRO banner at the present time derives partially from the forthcoming launch of COS-B (see *Nature*, **249**, 398; 1974); but quite apart from this slightly parochial incentive it turned out that gamma-ray astronomy has indeed reached something of a landmark recently, and is now likely to fulfil some of the promise which it has held for so long.

Certainly throughout the 1970s we have heard repeatedly that the big breakthrough in gamma-ray astronomy 'is about to be made'. But the difficulties of first detecting any gamma-rays from outside the Solar System and secondly deciding from exactly which direction they are coming have made some of the premature claims ring rather hollow in recent years. One result of these difficulties has been a considerable broadening of the accepted definition of gamma rays in this context; some of the data presented at Frascati would have been equally well suited to a symposium about X-ray astronomy. Such definitions are, however, intrinsically arbitrary, and as long as the active observers know what they mean by gamma rays no harm is likely to result from a broadening of the definition.

Ironically, in spite of the intensive efforts made to detect gamma ray events from outside the Solar System the most impressive data gathered so far have come from a series of satellites designed to monitor events on Earth. These, of course, are the Vela satellites, which are intended to detect radiation from nuclear explosions on Earth. Over the past four years, these satellites have not had the opportunity to discover many terrestrial nuclear explosions; but the same laws of physics apply to nuclear explosions elsewhere in space, where bursts of gamma rays are produced. As a result, the various Vela satellites have marked all of the 30 or so gamma ray bursts which have been recorded so far. And in only a couple of cases was it necessary to

A recent symposium provided an insight not only into the present status of gamma-ray astronomy, but also into the conventions of scientific symposia, as John Gribbin reports.

examine the Vela data in the light of evidence gained from other satellites before the evidence of the bursts became clear.

So gamma-ray astronomy can definitely be said to have cleared the first hurdle, of detecting something definite. The second problem has also been at least partially resolved since the proliferation of satellites equipped to detect gamma-ray bursts has made direction finding, by a kind of astronomical triangulation, a feasible proposition. And this, more or less, is where the Frascati symposium comes in. Other topics were also discussed, covering the gamma-ray background, low energy gamma-ray astronomy, and galactic emission. But to an observer from outside the gamma-ray astronomy family, the bursts and their interpretation provided the dominant interest.

I. B. Strong (Los Alamos) reviewed the observational data concerning the bursts, and other contributors elaborated on specific measurements before F. Pacini (Frascati) reviewed theories relating to their origin. In both branches of the investigation, the pioneering nature of gamma-ray astronomy was clearly apparent—but the effect of this on experimentalists and theoreticians differed greatly.

In a very real sense, gamma-ray astronomy is the last frontier of observational astronomy. It is now possible to observe every part of the electromagnetic spectrum, and the gamma-ray region is the last for which practical techniques have been developed. The observers, many of whom have a background in particle physics rather than in astronomy, seem somewhat overawed by this, and perhaps by the long struggle they have had to get hold of any worthwhile data. The result is that each observation seems to

be exhaustively analysed and picked over for significance—and the danger, of course, is that too much might thereby be read into what may well be atypical, or even incorrect, data.

The theoreticians, however, have fewer inhibitions. Indeed, a great many theoretical astronomers delight in a situation where there is just enough evidence to make model building worthwhile, but not enough to prove that their favoured model is incorrect. The study of gamma-ray bursts today provides a happy hunting ground for such theoreticians.

The fondness of the observers for smothering detail extended even to the presentation of their contributions at the conference. In the most extreme cases, we were told openly that although only a short paper was being presented, the version in the published proceedings of the conference would be much more 'complete'. That hardly seems fair on participants (some of whom had come from the United States and Japan), let alone on the humble reporter. In addition, many of the observations seemed essentially to duplicate one another, so that we had a stream of speakers standing up and saying much the same things about various events observed by different satellites, and showing graphs which seemed to be essentially interchangeable, allowing for the largish error bars.

It this kind of presentation really necessary? Clearly, each group must present its results and have them published in the proceedings of such a key conference, or the holders of the purse strings will want to know what is going on. But if each group had provided a summary of its data, circulated to participants in advance, and one or two speakers had outlined the implications then I feel sure that the symposium would have been just as fruitful, and perhaps a lot less tedious in parts.

Much the same could be said about most scientific symposia. But in the case of gamma-ray bursts such a streamlining of the proceedings would have been particularly apt, since only about three things are known about the bursts. First, they occur about seven times a year. Second, they are

very sharply defined in time with perhaps a double structure. And third, on the basis of 12 direction measurements, their distribution seems isotropic.

Of course, much more in the way of detailed measurements is available, and was presented. But that is just about all the evidence on which the theoreticians can build their models. Nothing daunted, the theoreticians have proceeded to do just that, as Pacini described.

The isotropy of the burst distribution provides vital information. Either the bursts originate nearby (a few hundred parsecs from the Sun), or they must be extragalactic. The intermediate case, of a distribution over a large part of our Galaxy, would reveal structure related to the structure of the Galaxy. With that proviso, Pacini happily listed the models which have been proposed: radiation from relativistic dust grains entering the Solar System; comets falling into collapsed stars; traces of "defunct" pulsars; superflares on stars; supernovae in external galaxies; birth of neutron stars; and the "first manifestation" of radio outbursts in external galaxies.

It does not really matter which, if any, of these models may turn out to be correct. What is significant is that theoreticians are prepared to toss such ideas into the melting pot, throwing them out or revising them as observations require. The observers, on the other hand, seem to wish to build complete detailed models on the basis of incomplete data, while justifying the procedure with a barrage of statistics (not always valid for small samples) and the interchangeable, large-error graphs which I have already mentioned.

Perhaps this is a result of the lack, in some cases, of astronomical training. With experiments which simply cannot be repeated and the everyday hazards of balloon and rocket observations, something more of the pioneering attitude seems to be needed in this last frontier of observational astronomy.

But on the other hand, this earnestness among the observers is really only manifested when they get up on their hind legs to address a gathering of

Glaxo awards

JOHN Gribbin, of *Nature*, is among the four recipients of Glaxo Travelling Fellowships for science journalists announced on July 9. His award, in the National category, is chiefly for a series of articles on the significance of climatic change; much of this work has appeared in *The Times Science Report* and longer articles appeared in *Nature*, *New Scientist* and *Environment and Change* during 1973.

The awards, which are sponsored by Glaxo and administered in collaboration with the Association of British Science Writers, are in the form of £500 travel grants; John Gribbin will be using his award to travel to the United States and Canada during the autumn, and will be reporting for *Nature* on research into climatic

John Gribbin (left) lives by the sea at Brighton.

change being carried out there.

John Gribbin joined the staff of *Nature* in October 1970, after completing research for a PhD in astrophysics at the University of Cambridge. In that year, he received the First Award of the Gravity Research Foundation of New Boston for work on "Using Gravity to Determine the Nature of Superluminous Astronomical Objects"; for most of the past four years he has been in charge of the *Nature-Times News Service*, which reports on developments in all the sciences. As well as the interest in climatic change which has led to this award, John Gribbin is concerned about the application of science to other global problems, and is co-author of a book on earthquakes and earthquake prediction (*The Jupiter Effect*) which is to be published by Macmillan in September.

Fellowships in the other three categories (Radio and Television; Regional; and Trade, Technical and House Magazine) go to David Wilson (Science Correspondent of BBC Television News), Judith Hann, a freelance science journalist, and Geoffrey Watts, Deputy Editor of *World Medicine*. Miss Hann is the first person to win a Glaxo Fellowship for the second time; the first occasion was in 1967.

Last year's award winners included John Maddox, then Editor of *Nature*, in the National category.

their peers. Individually or in small groups (especially after lubrication with the local Frascati wine) they appeared as intelligent people with the sense of humour needed to cope with the rigours of their trade. In some cases, they even agreed that their data were really rather vague and open to other interpretations, at least in detail.

The symptoms are, indeed, very similar to those severe cases of jargonese which result when many people try to write a "scientific paper". In the long term, the answer to both problems must lie in a basic change of attitude in the direction of clarity and honesty of communication as opposed to cunning packaging which can only be interpreted by the initiated.

In the short term, since almost every scientist is willing to communicate as a human being on a face to face basis, saving the 'scientist' mask for lecturing,

a solution might be to cut down on formal presentations at symposia, in favour of circulation of papers together with ample opportunity for informal discussion. At Frascati, more than 50 talks were on the official timetable (covering 2½ working days) and more were crammed in at short notice. Apart from the obvious benefits of a trip to Italy in June, it is difficult to see how the participants would have been less well served simply by reading the papers. The advantages of a symposium should be personal contact and the opportunity to assess the abilities of colleagues in the same field who may work on another continent; it seems that the time has certainly come when a move away from the present system, in the direction of the original "drinking party" implications of the word "symposium" could well be a good thing.

international news

EVER since the United States Supreme Court ruled last year that abortion is essentially a private matter between a woman and her doctor, a coalition of organisations campaigning under the banner of the 'Right of Life' movement has been trying to make it again a criminal matter between a woman, her doctor and the courts. The prime objective of the campaign is to get Congress to pass an amendment to the constitution to "protect the life of the unborn", but the chief casualty so far, much to the consternation of many biomedical scientists, is research of human foetuses.

The list of restrictions which have been placed on such research is impressive. Congress last month passed a bill which imposes a four-month ban on research on living foetuses while a special commission will draw up ground rules under which foetal research should be funded. The National Institutes of Health (NIH), which claims that it does not support research on live, aborted foetuses anyway, is drafting regulations governing all research of human subjects, including foetuses. An amendment has been put into the authorisation bill for the National Science Foundation (NSF) forbidding that agency to support research on live foetuses. (Backers of the amendment were evidently unmoved by protestations that NSF has never been in the business of funding foetal research, and does not intend to be.) On June 26, a bill was signed into law in Massachusetts which makes it a criminal act for anybody to carry out research on living foetuses there. And finally, a law has been on the books in Illinois for a year now which forbids research on all "aborted tissue" in that state.

Aside from the Illinois law, which imposes a blanket ban on all foetal research, the restrictions and prohibitions apply chiefly to two areas of study. First, they rule out research on foetuses aborted during mid-pregnancy which are delivered with their hearts still beating but which are insufficiently developed to remain alive for more than a few seconds or minutes. And second, they ban most research projects on foetuses while they are still in the womb. It is the latter area which is at the centre of most of the disputes, for research on foetuses *in vivo* has already produced some shortsighted and ill-founded conclusions.

At the federal level, the issue of

Foetal research aborted in United States

by Colin Norman, Washington

foetal research burst into the public spotlight last year following newspaper reports that NIH was drawing up guidelines for research on living foetuses. The day after the report was published, Dr Robert Berliner, then deputy NIH director for science, told about 200 Catholic high school students who had descended on the NIH campus in protest that "we know of no circumstances at present or in the foreseeable future which would justify NIH support of research on live, aborted human foetuses." He added that no such research was then being supported.

Nevertheless, anti-abortionists in Congress, led by representative Angelo Roncallo, a republican from New York, proposed a series of amendments to various bills which would have ruled out entirely all federal support for research on living foetuses. It was largely to head off such restrictive measures that a provision which imposes a four-month ban on such research was put into a bill dealing with biomedical ethics. The bill, which cleared Congress late last month, simply states that the Secretary of Health, Education and Welfare cannot support research on a living human foetus, "unless such research is done for the purpose of assuring the survival of such foetus". While the ban is in effect, a special Biomedical Ethics Commission will draw up rules governing such research.

As for the Massachusetts law, its implications were neatly summed up last week by Dr Elizabeth D. Hay, Professor of Embryology at Harvard and past president of the Society for Developmental Biology, who pointed out that "the federal ban cuts off funding for foetal research, but the (Massachusetts) state law will put you in prison for up to five years".

Sponsored by William Delahunt, a young state legislator, and vocally backed by the Boston Citizens' Committee for the right to life, the original bill would have ruled out most foetal research in Massachusetts, but it quickly fell foul of the Boston scientific community, which ran an effective

lobbying campaign to make the measure less restrictive. In its final form, the bill prohibits research in Massachusetts on live human foetuses, before or after abortion, but it also contains two important exemptions. First, research will be allowed if it has potential therapeutic value to the mother or the foetus and, second, it does not ban diagnostic tissue from dead foetuses, provided that the mother's consent has been obtained.

Asked for their opinions on the various federal prohibitions and the Massachusetts law last week, a number of biomedical scientists offered two chief observations. The first is that foetal research has provided many very significant findings, and a good deal of direct benefit to public health. One piece of research which is often cited in that regard is the growing of polio virus in cells cultured from foetal tissue, for which Dr John Enders and Dr Thomas Weller won the Nobel Prize in 1965. The second is that it is inadvisable to legislate an overall ban on any area of scientific research—such matters are best dealt with by ethical review committees which, according to federal regulations, must be established to guide research in institutions which receive biomedical research funds from the government.

What, exactly, is going to be ruled out by the various restrictions? The first thing to be said is that the ban on research on foetuses whose hearts are beating after they have been aborted will have little effect in the United States because there is very little of that kind of research going on there. For one thing, the usual method of abortion during the second trimester is saline injection which usually kills the foetus. Some research on foetal circulation and on the development of the immune system has, however, been carried out by American scientists in Scandinavia, where the preferred method of abortion during later stages of pregnancy is Caesarean section, and the federal ban will clearly rule out all NIH funding of such studies.

According to Dr David Nathan, a scientist at Boston's Childrens' Hospital, and a leading opponent of the Massachusetts legislation, the chief result of the various prohibitions will be "two serious losses, one in the area of foetal pharmacology, and the other in the screening of teratogens and dangerous drugs", both of which will be ruled out by the bans on research

THE launching of the space station Salyut 3 on June 24, 1974, and the successful docking with it of Soyuz 14 and the transfer of the two-man crew on July 5, marks a resumption of the Soviet programme of manned orbital space stations which was tragically interrupted in June, 1971 with the death of the three-man crew of Salyut 1 during re-entry.

In the three year moratorium, modifications have been made both to the Salyut station itself, and to the Soyuz programme which supports it. The re-designed Salyut was officially flight-tested (unmanned) during April 1973. This craft incorporated modifications to the solar panels (three panels rotatable through 180°, instead of the previous four) and to the optical ground-viewing systems. In addition to this "official" test (Salyut 2), other craft of the series have almost certainly been tested, unnamed, under the cover-all of the Kosmos programme.

The Soyuz, too, was almost certainly tested out as a number of Kosmos satellites (numbers 496, 573, 613, in particular, are widely considered to have been unmanned Soyuz craft) before manned testing was resumed with Soyuz 12 (launched September 29, 1973—a two-day flight) and Soyuz 13 (launched December 18, 1973—an eight-day flight).

The principal modification to the resumed Soyuz programme was the use of a two-man, rather than a three-man crew. In view of the cause of the Salyut 1 tragedy—the failure of a seal and loss

Cosmonauts Popovich and Artyukhin reporting ready for take-off on July 4th.

of cabin pressure during re-entry, this is almost certainly intended as an additional safety precaution, providing the additional space needed for the crew to wear spacesuits during re-entry. This policy is continued with the latest flight, and it is significant that the *Pravda* picture of cosmonauts Pavel Popovich and Yuri Artyukhin, apparently inside the Soyuz cabin, shows them in space suits.

The official aims of the test according to the Tass reports are: "Further elaboration of the improved construction of the station and also of the on-board systems and apparatus, and the conducting of scientific and technological investigations and experiments in cosmic flight". This includes observa-

tions of geomorphological features of the Earth's surface and atmospheric phenomena, investigation of the physical parameters of space, and medical and biological studies of the effect of "the factors of space flight on the human organism and the 'determination of rational regimes of the crews working' on board."

This last aim seems to be of particular significance in view of the joint Apollo-Soyuz mission planned for next year. Although the official aims make no specific mention of this, the timing of the flight, to coincide with President Nixon's visit, is surely intended to imply that the Soviet preparations for the joint United States-USSR mission are well in hand.

on foetuses before induced abortion.

Specifically prohibited will be research projects which, for example, involve the administration of drugs or vaccines to a pregnant woman scheduled to undergo an abortion, in order to see whether they cross the placental barrier and affect the foetus. Such studies have, however, produced some extremely important findings.

A study carried out in Helsinki and reported in 1972, for example (Vaheri *et al.*, *New Engl. J. Med.*, **286**, 1071; 1972) showed that virus from rubella vaccine can cross the placenta and enter the foetus. The research, which consisted of vaccinating ten women before they had abortions and analysing the foetal tissue for signs of rubella virus, was described by a Harvard scientist last week as "fantastically important", since it provides very strong evidence against vaccinating women during early stages of pregnancy. The research was particularly significant since previous studies had indicated that the virus from the rubella vaccine does not cross to the

foetus through the placenta.

It is also worth pointing out that four doctors are now awaiting trial on criminal charges arising from a research project they conducted at Boston City Hospital in 1971 and 1972. The study consisted of administering antibiotics to 33 women about to undergo abortions to see which was the most effective in crossing the placenta. The idea was to find the best drug to use in place of penicillin to clear up foetal infections. But the four doctors were charged earlier this year with infringing an obscure 19th century Massachusetts law which was originally designed to prevent grave robbing. Although Delahunt said last week that his bill was in no way connected with those indictments, it is clear that if the grave robbing law is found ineffective in preventing such research projects the new Massachusetts law will certainly do the job.

Two chief arguments have been raised against such research, for one thing, it puts the mother who has consented to take part in the study in a

position in which it would be difficult to change her mind about having an abortion. And for another, it constitutes research on a human being (the foetus) without its consent, which is contrary to every code of biomedical ethics including the Nuremberg Code, which was promulgated in response to Nazi medical experiments. Such a view point rests, however, on the assumption that life begins at conception rather than at any other stage of foetal development—an issue which was deliberately left vague by the Supreme Court when it issued its historic abortion decision last year.

Dr Michael N. Oxman, a virologist at the Children's Hospital Medical Center in Boston, argues, however, that a ban on foetal studies *in vivo* "creates a situation where children are going to be put at risk rather than foetuses which are going to be aborted". He pointed out that if a vaccine or a drug administered during pregnancy crosses the placenta and harms the foetus, it would be better to know about it through research on

What that treaty means

LAST week Mr Nixon and Mr Brezhnev signed a treaty on the Limitation of Underground Nuclear Weapons Tests. It was probably the most substantial arms-control agreement to come from Mr Nixon's visit to Moscow and it bears some scrutiny.

- It is bilateral. There is no provision for any further country to attach itself to the treaty.

- After March 31, 1976 the yield of tests may not exceed 150 kilotons. The wording indicates that the United Kingdom, for instance, would not be allowed to test more than 150 kilotons on United States property.

- 'National technical means' will be used for monitoring and neither party will interfere with the other party's means. This leaves much obscure, particularly the question of what could be regarded as interference. If a test of 200 kilotons is fired in an appropriate environment to reduce the apparent yield as seen by a seismometer to 150 kilotons, is this interference?

- Peaceful explosions are excluded from the ban; negotiations on these will continue.

- The treaty must be ratified.

- Data shall be exchanged on the geological and geophysical environment of present test sites and of any future site. A tall order for an area as complicated as southern Nevada.

- Locations of tests shall be exchanged after firing. But the United States, and doubtless the Soviet Union, test many devices much too small to be monitored by national technical means. Are these to be included?

Open symbols—Soviet tests. Filled symbols—U.S. tests. Circles—weapons tests. Stars—peaceful explosions. The dashed line roughly represents a yield of 150 ktons.

- Yields of two tests in each geographically distinct area will be exchanged for calibration purposes.

Reaction amongst those with a long-term interest in a test ban has been bitter. The treaty is blatantly bilateral—there is no provision that any of the data exchanged need get beyond Kremlin and Pentagon files. The extraordinary length of time before the treaty comes into force permits no end of significant tests to be performed at leisure. The threshold is much higher than anyone had believed possible. The figure shows testing

activities for the last four years. It is difficult to relate yield to seismic magnitude in a unique way, because of varying geological environments, but a value of 5.9 might roughly represent 150 kilotons. It is obvious how much testing will still be permissible. But the thing which most people are perturbed about is the way this treaty appears to close out, at least for the immediate future, any thought of a comprehensive ban. The United Nations Disarmament Conference in Geneva will hear some vigorous opinions from the other nuclear powers and the potential proliferators in the next two months.

foetuses about to be aborted rather than through damage to children.

As for the exemptions in the Massachusetts legislation, opinion is divided on how effective they will be in allowing potentially valuable research to take place. Nathan, who last week praised Delahunt's willingness to compromise on the bill, welcomes the provision which allows research on diagnostic techniques likely to be of value to either the mother or the foetus. The exemption will allow research aimed, for example, at developing a foetoscope capable of 'taking foetal samples for the diagnosis of such diseases as cystic fibrosis and Cooley's anaemia.

But other researchers have pointed out that many valuable techniques and research findings have been developed from research which at the time it was conducted had little potential benefit

for that particular pregnancy. The technique of amniocentesis—removal of fluid from the amniotic cavity—which has led to identification of more than 50 diseases before birth, for example, was used first to measure intrauterine pressure during labour, and would probably never have been developed under the terms of the Massachusetts law. That piece of research would definitely have been ruled out under the terms of the federal ban on foetal research since it was not aimed at "assuring the survival" of the foetus.

Finally, many researchers are concerned that restrictions in foetal research, particularly when they carry possible criminal penalties—the Massachusetts law makes live foetal research a crime punishable by 1–5 years in prison—will drive good scientists away

from important studies. Oxman said, for example that the Massachusetts bill "creates an unfortunate atmosphere in which a good researcher will decide to do something else. The loss could be serious."

Mark V marks time

The University of Manchester has announced "with regret" the decision by the Science Research Council that it will not be able to accommodate the cost of the proposed Mark VA telescope at Meiford, Wales, in its budget "over the next few years". Tenders for the 375-foot instrument indicate a cost of £16–£17 million; the SRC and the University will now have discussions in the near future about more modest possibilities for developing the progress of research at Jodrell Bank.

As a doctor and researcher in medicine and bioelectronics who has always stressed the human mission of medical science and the necessity for international cooperation, I am appealing to you for moral support in my apparently hopeless endeavour to return to active and creative scientific work. For four years now I have been refused all opportunities to work scientifically and professionally in my country and for this reason I applied in 1972 to our Ministry of Health for permission to work abroad. After a year's delay, permission was refused. I have recently sent a new application to the Ministry of the Interior asking for a long term permit to work at research institutes in the United States or West Germany; in the event of this permit being withheld, I have applied to emigrate.

I have been led to this decision by bitter experience with Czechoslovak officialdom and employers, and by the realisation that, as a citizen who in 1968 supported the humanistic reform of socialism undertaken under the leadership of A. Dubcek, I stand no chance in my own country of making any contribution to society according to my skills.

Following the change in leadership of the Czechoslovak Communist Party and the change in party policy, all kinds of repressive measures were, as is generally known, instituted against supporters of the democratic reforms. I suffered harsh reprisals in 1970, when the Minister of Health, without stating any grounds, ordered my immediate dismissal from the post of Director of the Research Institute for Electronics and Modelling in Medicine, the institute which I founded and built up. Then an unprecedented check-up was made in the institute in order to gather evidence against me concerning its economic management. The intentions underlying this action were obvious, and I would be willing to publish the evidence should circumstances demand. At the same time officers of State Security carried out an extensive investigation of many staff members of the institute, and I myself was subjected to repeated interrogation.

Since 1970, after dismissal from the directorship, I have not been allowed to engage in research, experimental or teaching work of any kind, and since 1971 I have even been banned from clinical work. In 1972, on returning from a spell of sick leave, I was not allowed to resume work at my place of employment, although such an order was in contravention of valid Czechoslovak law. I was also banned from publishing anything at all. Scientific papers in the press had to be thrown out, and my name had to be deleted from collective works or was deleted by the censors. Nor can my name

appear in literary references.

By degrees I was expelled from all Czechoslovak professional societies, from membership of the editorial boards of scientific and popular scientific journals, from the Collegium of Medical Sciences, from the Scientific Council of the Ministry of Health and from all technical commissions, and I was banned from lecturing at Prague and Brno universities and at the Prague Institute for Further Education of Doctors and Pharmacists. I am officially excluded from participating not only in conferences abroad but also in medical conferences and meetings at home.

For a full four years I have tried to find a place in society in accordance

**I have been subjected
not merely to social
discrimination but also
to a form of protracted
and total spiritual and
intellectual liquidation
against which I have
no defence**

This is the text of an appeal addressed to the World Federation of Scientific Workers by Bohumil Peleska, a Czech scientist

with my qualifications, I have paid dozens of visits to officials of the Communist Party, to political offices, and to government and public institutions, I have made dozens of proposals as to how I could be employed. All efforts have been in vain, and equally fruitless have been applications to employing organisations; they always cite orders from superior departmental and political bodies. No account was taken even of the fact that, in the course of twenty years of work in this field of research, I built up the Experimental Department of the Institute of Clinical and Experimental Surgery, that I founded and built up the Research Institute for Electronics and Modelling in Medicine, and that I was awarded by the President of the Republic in 1959 the Order of Merit for Services to Construction and in 1965 the Klement Gottwald State Prize for research, nor that I have published 150 scientific works.

The persecution culminated in 1974

when, in contravention of the Labour Code, I was dismissed from my employment under Article 46 on the grounds that I had committed a breach of the social order by my political attitude in 1968. Knowing that colleagues who had suffered dismissal under this Article were in financial straits and searching for jobs, I appealed against the dismissal, but my employers and the trade union refuse to rescind this illegal act, so that now I am not only barred from scientific and professional work—I am unemployed and have no prospects of being able to earn a living for my family, which includes three young children. That is how things are, although the Communist Party and the Czechoslovak government officially maintain that nobody can be made to suffer on account of their political views.

I have been subjected in recent years to a procedure which I consider to be not merely social discrimination but also a form of protracted and total spiritual and intellectual liquidation against which I have no defence at present. The feeling that the rights guaranteed by the Constitution and the Labour Code are inaccessible has convinced me that further efforts to find work in my profession would merely involve further loss of time and of the creative years of my life.

Having, for four years, been banned from scientific and professional activity, from publishing and teaching in the field of medicine and bioelectronics, having been illegally dismissed from my employment and having been repeatedly interrogated by State Security, I have lost the sense of legal and personal security; this has induced me to apply to the Czechoslovak authorities for a long term permit to work abroad, accompanied by my whole family, a step which I prefer to emigration. This demand is in accordance with the spirit of the Charter of Human Rights of the United Nations, on ratifying which the Czechoslovak government also undertook to observe and implement it.

As my previous application was rejected, I am approaching you, not only as an administrative body but also as the conscience of the world community of scientific workers; I ask for moral support in my endeavour to return to scientific life and creative work. Through the widespread and unselfish cooperation among scientists the world over, the fruits of medical research are part of the common cultural wealth of all mankind. Thus no power on Earth has the right to curb, prevent or forbid free scientific cooperation in medicine, or to isolate scientific workers and treat them as serfs merely because they wanted a little more freedom, but not nearly as much as they are entitled to as human beings.

Synchrotron radiation facility

SIR,—After reading the article by John Gribbin (*Nature*, April 12) on the proposal for a new synchrotron radiation facility, I am wondering if he and I went to the same meeting. Certainly the meeting I attended did not show clearly that the proposal to build a new £2 million storage ring “needs careful rethinking” or that “the plan as originally envisaged seems unlikely to survive”. At the conclusion of the meeting, the physicists, chemists, biologists and metallurgists present made it overwhelmingly clear that they firmly supported the existing SRC plans.

The project is not at the early stages of planning. Indeed, the scientific case for a dedicated storage ring has been established over a considerable period of time, accepted by the Science Board of SRC and a design study costing £70,000 is already well under way.

Storage ring facilities being built in Hamburg and Paris are such that synchrotron radiation users will have limited access and remain parasitic. What is envisaged in the United Kingdom is a unique facility, with 10 access points and accommodating 30 experiments simultaneously. Many experiments which could not previously be performed due to lack of intensity now become feasible. New experiments utilising the polarisation properties of synchrotron radiation have been proposed, and the enormous flux in the 1 Å region will allow time resolution of milliseconds or better in the study of complex biological functions, such as muscle flexing. The storage ring is also expected to be a potent source for scattering experiments below 1 Å.

What the scientists present at Reading were extremely concerned about was the time scale involved in building a dedicated storage ring. The building of such a facility could in principle be started almost immediately because no major new technological advances are envisaged (I omit consideration about the “wigglers” required to reach the shorter wavelengths). It need not be built at Daresbury and therefore need not await the closure of NINA. This would ensure that the United Kingdom has its share of new and exciting physics. Is it realistic, however, to suggest such an alternative? The estimated cost of £2

million would raise, since a new building to house the storage ring, and all the services available in the NINA facility, would have to be provided. Incidentally, Professor Bleaney’s suggestion of a disastrous 5 year period between NINA closure and storage ring commissioning was refuted by Daresbury personnel present. A preliminary estimate is 12 to 18 months, given the level of funding shown in the SRC document. This could be reduced with sufficient manpower and money if SRC were to give whole-hearted support to the proposal.

It is now up to the SRC to act swiftly and decisively in this matter or the United Kingdom will once again find itself an also-ran in the race for scientific discovery. The critics have had their chance to comment on the proposal and no substantial argument was forthcoming. (For example, nobody has suggested that a tunable soft X-ray laser will turn such a facility into an under-used white elephant.) In the absence of such criticism, let us press ahead with a facility which will surely be the envy of synchrotron radiation users throughout the world.

Yours faithfully,

K. CODLING

We have also received another letter in similar vein from seventeen of those at the Reading meeting.—ED.

Penicillin

SIR,—I am grateful to Ernst Chain for his comments on the rediscovery of penicillin (*Nature*, June 14). There would, however, seem to be ample justification in the literature for the viewpoint I put forward in my earlier article (*Nature*, May 24) concerning the direction of research into antibiotics during wartime and the quest for agents of chemotherapy. Chain’s first joint paper in the field¹ refers to chemotherapy in title and substance, and his later joint publication that same year (on penicillinase) discusses the relative merits of penicillin as an agent of chemotherapy². The extensive paper on therapy using penicillin published some months later by Chain and the other members of the Oxford team³ expands on the theme. The effects of the war effort, to which I have referred elsewhere⁴ is repeatedly emphasised in Fleming’s classic volume⁵

(to which, apparently, the Oxford workers declined to contribute). Bacharach and Hems⁶ in particular, state that penicillin seemed to “merit much more attention than it had received”, a pointer to exactly the form of directed research I would like to see in oncology. It contrasts radically with Coghill’s comments⁷ that Raistrick, apparently the first to see the significance of antibiotics, “could get no clinical tests made”. Perhaps the essence of what we should say is that, though it is widely assumed that Fleming’s fortuitous discovery gave rise to the concept of antibiosis, the discovery of *Penicillium notatum*, and the first recorded examples of ‘microbial therapy’, it did not in fact originate any of these⁸. In this respect the research work of Howard Florey and Ernst Chain, with their coworkers, was of peerless importance.

Yours faithfully,

BRIAN J. FORD

Wursted

SIR,—We are not in complete agreement with Neidle’s point (*Nature*, **249**, 212; 1974) that there is a cultural bias in the understanding of our “hotdog” model for repressor-operator interaction. The Germans, for example, might consider it the *Wurst* model of operator-repressor binding.

The briefer the letter the better its chance of being published. We reserve the right to cut correspondence.

news and views

Ophiolites and oceanic lithosphere

THE most obvious way of testing whether present-day ophiolites represent ancient oceanic crust and uppermost mantle is to compare the properties of such sequences with those of modern oceanic lithosphere. The scope here is wide; and comparisons have already been made in terms of geology, petrology, chemistry, magnetic properties and seismic velocities. Unfortunately, however, the results of these attempts at correlation have not been entirely conclusive because comparisons have proved to be less straightforward than had originally been hoped. No doubt it is easy to be wise after the event; but it is clear in retrospect that some of the, as yet incompletely fulfilled, hopes expressed in the early literature of the subject were based on overly-naïve expectations even if it must be admitted at the same time that some of the subsequent investigations have been afflicted by peculiarly bad luck. But be that as it may, the fact is that comparisons between ophiolite suites and modern ocean floor are likely to encounter some quite obvious difficulties even if it is assumed that present and past oceanic lithosphere were produced by comparable processes.

Problems arise partly because even if ophiolite sequences were submarine in formation they are now subaerial in fact; and so comparison with modern ocean floor means comparison between structures under quite different circumstances. The effects of differing conditions become quite evident when, for example, Matthews *et al.* (*Nature*, **231**, 200; 1971) measured seismic velocities in the outcrops of the Troodos Massif of Cyprus in the hope that they would be similar to the velocities in the layers of the oceanic crust. In fact, the velocities determined were "surprisingly low"—so low that almost all of them, including those in the ultramafics at the bottom of the sequence, were comparable to those in oceanic layer 2 alone. The conclusion that Matthews and his colleagues came to was that the low velocities were probably due to the presence of open cracks in the rocks under very low confining pressures—cracks which are presumably not present in *in situ* oceanic crust, at least in the lower layers. This view later received convincing support from Poster (*Nature phys. Sci.*, **243**, 2; 1973) who showed that ultrasonic velocities are higher in Troodos samples under pressures of up to 2 kbar.

Then there are the more direct effects associated with older material which has been uplifted and simultaneously subjected to considerable tectonic forces. Irreversible chemical changes may have taken place in some or all of the ophiolite components, making direct comparison with newer oceanic material impossible; and physical changes may have made it difficult to measure accurately even the simplest of parameters such as the thicknesses of the various ophiolite units. For example, although Poster found that the seismic velocities in Troodos samples increased with increasing pressure and thus approached more closely the velocities observed in oceanic crustal layers, he also found that even under pressure the velocities in the ultramafics forming the lowest layer of the ophiolite sequence were lower than those in the gabbros comprising the next layer up. Insofar as the velocities in modern oceanic layers in-

crease with depth, the comparison between the Troodos sequence and present-day ocean floor cannot therefore be considered entirely satisfactory. Poster's suggested explanation of this apparent anomaly was that the ultramafics have undergone a considerable degree of serpentinisation, a process known to lower grain density and consequently seismic wave velocity; and a study of the ultramafic samples in thin section confirmed that serpentinisation had indeed taken place.

So far, however, whenever there has been a discrepancy between a property of ophiolite suites and the corresponding property of oceanic lithosphere, it has seemed quite natural to suppose that the 'problem' originates with the ophiolites. Thus it was entirely reasonable for Poster to suppose that if the Troodos Massif is a remnant of Mesozoic ocean floor and yet exhibits an important difference from modern oceanic lithosphere, then something must have happened to the Troodos Massif. But what about the other half of the comparison? Up to now, it has apparently never occurred to anybody to question whether or not ophiolite sequences are actually being compared with the correct model of the ocean floor. On the face of it, of course, there is no reason why anybody should; the generalised oceanic crustal section proposed more than 10 years ago by Raitt (in *The Sea*, Interscience, 1963) has long been a part of the accepted wisdom of geophysics. But on page 136 of this issue of *Nature*, Moores and Jackson present a comparison between certain features of ophiolites and ocean floor which is apparently much more satisfactory than any proposed hitherto—and they do so on the basis not of the Raitt model but of a somewhat different structure proposed about 3 years ago in a little-noticed article by Sutton *et al.* (in *The structure and Physical Properties of the Earth's Crust*, American Geophysical Union, 1971).

What is still generally regarded as the standard model of 'typical' oceanic crust and uppermost mantle (that is, of ocean basins at normal depths away from ridges, trenches, seamounts and so on) comprises three layers below the unconsolidated sediments (layer 1). The values quoted for thickness and seismic velocity differ between authorities; but as originally given by Raitt, layer 2 has a thickness of 1.7 ± 0.8 km and a P wave velocity of 5.1 ± 0.6 km s⁻¹, layer 3 is 4.9 ± 1.4 km thick but possesses a much less variable velocity of 6.7 ± 0.3 km s⁻¹, and layer 4 (uppermost mantle) has a velocity of 8.1 ± 0.2 km s⁻¹. Layer 3 is usually regarded as the bottom layer of the crust, although from time to time some workers have interpreted marine seismic profiles as indicating the presence of a layer with a velocity in the range 7.1–7.6 km s⁻¹. This 'extra' layer has sometimes been described as layer 3 with anomalously high velocity and sometimes as mantle with anomalously low velocity (and even, on occasions, as the result of misleading data)—reasonable interpretations in most cases because either one or both of the 6.7 km s⁻¹ and 8.1 km s⁻¹ layers were apparently missing and/or the relevant profiles were obviously associated with a prominent feature such as a ridge or trench. In short, the intermediate velocities derived from marine profiles were generally dismissed as atypical and not very important.

But Sutton *et al.* came to a quite different conclusion. Using a new method of seismic refraction profiling involving a single ship, sonobuoys, a repetitive seismic energy source and continuous recording (the Asper method), they were able to identify a high velocity basal crustal layer

($7.4 \pm 0.3 \text{ km s}^{-1}$) at eight Pacific Ocean sites ranging from Fiji to the coast of California. Moreover, they were able to find in the literature reports of ten other sites in the Pacific, the Atlantic and the Mediterranean at which a layer of velocity about 7.4 km s^{-1} was sandwiched between a crustal layer of at least 6.0 km s^{-1} and an upper mantle layer of at least 7.7 km s^{-1} . In addition, there are numerous sites at which the 7.4 km s^{-1} layer had been identified but at which either layer 3 or the uppermost mantle had been missed or (in the case of the mantle) inferred from other data. As a result, Sutton and his colleagues proposed that a basal crustal layer about 3.1 km thick, far from being rare in the oceans (though quite familiar beneath continents), exists under all Pacific basins and probably under basins in other oceans as well. The reason why it is frequently missed even by more elaborate refraction techniques, they suggested, is that it appears largely as second arrivals masked by other arrivals. In other words, the situation is analogous to that in which difficulties were encountered in observing layer 2 during the early days of marine seismic refraction work; layer 2 only came to be observed regularly when conditions were arranged for a specific search.

When Sutton and his colleagues first presented their work at a conference at the University of Colorado in 1970, A. Hales praised them for their courage in reporting "some rather unusual mantle velocities" and, by implication, in proposing an important modification to a model which has come to be accepted as one of the near-certainties of geophysics. Since then, the article in which the results were described in greater detail has apparently received little attention. Moreover, even though confirmation of the basal crustal layer would, in the words of Sutton *et al.*, "have major significance for both interpretation of other geophysical data (gravity and surface waves) and speculations on the geologic processes that resulted in the formation of the Earth's crust", the possibility of such a layer has been little discussed. Presumably this is in part because the Asper technique is not yet in widespread use, so that few new results have been obtained. In the meantime, however, Sutton and his colleagues may take heart from the indirect evidence adduced by Moores and Johnson, for if the latter authors are right in their interpretation, the consistency between the Sutton model and the view of ophiolite suites as oceanic lithosphere brings support for both.

PETER J. SMITH

Picornaviruses still useful as model systems

JUST as the drift of molecular biology towards eukaryotic systems led to a return-to-*E. coli* backlash, so too the present trend of many virologists towards tumour virology led to the retort "polio is not dead" (Baltimore, *Perspectives in Virology*, 7, 1; 1971). Indeed, as model systems the picornaviruses have much to offer, and still produce regular surprises.

Porter, Carey and Fellner (*Nature*, 248, 675; 1974) have recently demonstrated the presence of a large poly(C) tract, about 90–100 residues long and with 85–90 C residues, within the RNA of encephalomyocarditis (EMC) virus. Since the molecular weight of the viral RNA exceeds by about 1,000 nucleotides that necessary to code for all the viral proteins, and because none of the known viral proteins is rich in proline, Porter *et al.* argue that the poly(C) tract is probably near to one of the termini of the molecule, in the untranslated regions. It is interesting that partially purified EMC RNA polymerase will synthesise poly(G) using exogenous poly(C) as a template (Rosenberg, Diskin,

Oron and Traub, *Proc. natn. Acad. Sci. U.S.A.*, 69, 3815; 1972) and this perhaps indicates a role for poly(C) in replication. Further support for this idea is given by the fact that bacteriophage Q β replicase will also transcribe poly(C) but cannot recognise other homopolymers. Q β RNA does not contain a poly(C) tract, however, and so the significance of these observations remains unclear.

Porter *et al.* have not been able to detect poly(A) in EMC RNA. A similar result was previously reported for the closely related cardiovirus, Mengo (Miller and Plagemann, *J. gen. Virol.*, 17, 349; 1972), but is in contrast to results with poliovirus, an enterovirus, which contains a poly(A) region of 50–100 residues at its 3' terminal (Yogo and Wimmer, *Proc. natn. Acad. Sci. U.S.A.*, 69, 1877; 1972). The reason for this difference between the RNAs of different picornavirus subgroups is puzzling, particularly since it is known that the proteins coded for by the various viral RNAs and their gene order along it are very similar. An understanding of the requirement for poly(A) in the messenger RNAs of viruses which replicate in the cytoplasm might give some clue as to the role of this structure in normal mRNA; on the other hand it is possible that the poly(A) in viruses has a different function to that of the host, for example in viral assembly.

Many plant viruses contain a transfer RNA-like structure covalently linked to the genomic RNA, which can be enzymatically aminoacylated. The tRNA-like structure is present at the 3' end of the RNA, and is different in primary sequence to the corresponding host cell tRNA molecules. The function of these structures is unknown but they are able to interact with several of the enzymes involved in protein synthesis. Salomon and Littauer (*Nature*, 249, 32; 1974) have now reported that mengovirus RNA can be acylated with histidine, by aminoacyl synthetases from mouse liver. Similar enzymes from *E. coli* were unable to produce this result. That the material acylated by the liver enzymes was not contaminating host tRNA was shown by polyacrylamide gel electrophoresis under denaturing conditions. Although cleavage of the viral RNA occurred during aminoacylation, the viral fragment containing labelled histidine was significantly larger than host cell histidyl-tRNA. It is not yet known whether cleavage of Mengo RNA is necessary for charging with histidine or is an artefact caused by contaminating RNases.

Since poliovirus RNA terminates in poly(A) at the 3' end, it cannot have a tRNA-like structure in that position, and not surprisingly previous attempts to aminoacylate polio RNA have failed (Oberg and Philipson, *Biochem. biophys. Res. Commun.*, 48, 927; 1972). This observation therefore serves to emphasise the differences that I have mentioned between the RNA of the cardio and enteroviruses within the untranslated regions.

Earlier experiments have tended to support a role for aminoacyl-viral RNA in protein synthesis. Indeed, the 3' terminal portion of turnip yellow mosaic virus (TYMV) RNA donates valine into polypeptide in a cell-free system (Haenni, Prochiantz, Bernard and Chapeville, *Nature new Biol.*, 241, 166; 1973). The physiological significance of this finding, however, has been questioned by Shih, Kaesberg and Hall (*Nature*, 249, 353; 1974) who made use of the fact that brome mosaic virus RNA can act as a messenger *in vitro* to give well-defined virus-coded products and can also be aminoacylated with tyrosine. Both these activities were examined after chemical modification of the 3' terminus of the viral RNA. As expected, such modification completely abolished the ability of the RNA to accept tyrosine, but surprisingly had virtually no effect on the protein synthetic activity of the viral RNA nor on the authenticity of the cell-free product. Thus Shih *et al.* feel that this eliminates any role for aminoacyl-viral RNA as an obligatory requirement for viral protein synthesis, and instead favour a regulatory role for the tRNA-like structure.

Since protein synthesis elongation factor 1 recognises aminoacyl-tRNA and is also involved in RNA synthesis (at least in bacteria) then perhaps the aminoacylviral RNA is somehow used to integrate protein and RNA synthesis in virus-infected cells.

Two technical problems should be borne in mind, however; first, Salomon and Littauer could only charge about 20% of their Mengo RNA with histidine, and, second, cell-free protein synthesis systems are so very inefficient compared with whole cells that any subtle effects which might be caused by tRNA 'modulation' *in vivo* may be completely lost *in vitro*.

ALAN E. SMITH

258,247 dam earthquakes

by David Davies

BUILD a large reservoir and expect earthquakes. This has been a common experience in the past 20 years. The Koyna Dam in India and the Kariba Dam in Africa both triggered off much seismic activity and there have been many other similar cases. A well-documented example in China is now presented by Shen Chung-Kang in a recent issue of *Scientia Sinica* (17 (2), 239–272; 1974).

The Hsinfengkiang Dam in Kwangtung Province was started in July 1958 and by August 1960 was producing electric power. The reservoir covers 390 km² and impounds 11,500 million m³ of water. The dam is 440 m long and has a maximum height of 105 m. The immediate vicinity was no more seismic before the construction of the dam than any other area in China, where there is, of course, much scattered seismicity.

Within a month of the first impounding of water in October 1959, seismic activity started up and as the water level rose so did the frequency of quakes. Many of the earthquakes could only be detected instrumentally, but a few were felt in the area around the dam—these generally had a surface-wave magnitude of 2 to 3. A set of seismometers was moved into the area to enable accurate locations to be produced and these still operate.

The first earthquakes were in the region of the dam itself, but progressively the activity spread to other regions. Relatively few events were located under the water itself, the majority being within a kilometre of the water's edge on the landward side. Each new rise in water level seemed to stimulate fresh activity; the depths of the earthquakes were typically 4 or 5 km. Finally in March 1962 came a magnitude 6 event within 1 km of the

dam and 5 km deep. The intensity at the epicentre was VIII—a violent shock, but the dam survived since it had been strengthened months previously on the basis of the earlier activity.

In the last 20 days before the main shock there was a marked reduction in activity everywhere in the reservoir region, and those small earthquakes that there were began to move towards the epicentre of the main shock. Since March 1962 aftershocks have continued with characteristics conventionally expected of an aftershock sequence and the activity in the area continues to this day. Up to 1972, 258,247 shocks with Ms greater than 0.2 were recorded.

What causes reservoir earthquakes? The best general explanation put forward so far, which the author also favours, is that water percolates into the underlying rocks and finds its way into groundwater channels and deep fissures. As the seepage pressure rises the water acts as a means of lubricating, as it were, the faults in the region. Thus earthquakes are facilitated as slippages along these faults. Such an explanation in terms of pore interstitial fluids, is increasingly being favoured as a general explanation of tectonic earthquakes.

Healthy carriers of hepatitis B

from Arie J. Zuckerman

Medical Virology Correspondent

NUMEROUS seroepidemiological surveys on selected groups have shown that the prevalence of hepatitis B antigen, a marker of infection with hepatitis B virus, in apparently healthy persons in Western Europe and North America is 0.1–0.6% by comparison with 5–20% in tropical Africa, South East Asia and the Far East (*Tech. Rep. Ser. Wld Hlth Org.*, No. 512; 1973). Although relatively little information is available from serial samples collected over a period of time, which would permit more precise determination of the carrier rate in defined populations, the implications are that there may be tens of millions of individuals throughout the world who carry silently in their serum the hepatitis B antigen. For practical purposes it has been agreed that a persistent carrier state exists in persons in whom the antigen has been detected repeatedly for more than 3 months. The carrier state may be life long; Zuckerman and Taylor (*Nature*, 223, 81; 1969) described the

Tidal drag cannot move plates

from Peter J. Smith

Geomagnetism Correspondent

THE idea that continents might be displaced by tidal forces was discussed at some length by Wegener in various editions of his book *The Origins of the Continents and Oceans*. But ever since Jeffreys (*The Earth*, Cambridge University Press, 1929) showed that the stress over the Earth's surface arising from tidal friction is only of the order of 10^{-4} dyn cm⁻², few people have considered tidal drag a likely driving mechanism for continental drift or plate motions. On the other hand, such a mechanism does seem to be feasible from the energy point of view. Recent calculations suggest that the energy dissipated tidally may exceed 5×10^{19} erg s⁻¹ (Rochester, *Eos*, 54, 769; 1973), of which about 2.5×10^{19} erg s⁻¹ is likely to be the maximum dissipated in shallow seas and of which less than 10^{18} erg s⁻¹ is lost in the solid Earth. Thus, in principle, as much as $2-3 \times 10^{19}$ erg s⁻¹ might be available for driving plates.

Recently, Bostrom (*Nature*, 234, 536; 1971) and Moore (*Geology*, 1, 99; 1973) have revived the tidal drag mechanism, citing in its support such phenomena as the dependence of seismicity on latitude

and the tendency of oceanic ridge segments to lie north-south (with transform faults lying east-west). But Jordan (*J. geophys. Res.*, 79, 2141; 1974) has now carried out a 'simple calculation' showing that although a plate velocity of 5 cm yr⁻¹ would involve the dissipation of energy at a rate of only 0.8×10^{17} erg s⁻¹ (well within the amount available), a torque of 10^{33} dyn cm would be required to maintain it. The actual couple exerted on the Earth by the Moon is probably less than 10^{24} dyn cm, or 9 orders of magnitude too small to allow plate motion if currently quoted values of asthenospheric viscosity are accepted. Tidal forces could produce lithospheric motion, but only if the viscosity of the asthenosphere were to be as (unbelievably) low as 10^{11} poise.

In further support of the view that tidal forces are not relevant to present-day plate tectonics, Jordan cites recent plate models based on the fixed hot spot hypothesis, which suggest that the westward displacement of the lithosphere as a whole is small compared with the relative motions of plates. In the meantime, however, all this leaves open the rather different question of what happens to the balance of the energy released by tidal friction.

case history of a well documented former blood donor who has been a healthy carrier for more than 20 years.

In high prevalence areas, for example in tropical countries, the antigen is detected in individuals of all ages, most frequently in children. The prevalence of antigen in Caucasians living in some tropical areas is higher than those in temperate zones yet it is considerably lower than in the indigenous population. In all regions the antigen is reported to be more frequent in males than in females and in urban than in rural communities. The universal problem which the carrier state poses to blood transfusion and other medical services, to morbidity from liver disease and to health in general, requires no elaboration. Yet the mechanisms leading to the formation of the carrier state are little known.

In a recent study by Gerety and his colleagues (*J. Pediat.*, **84**, 661; 1974), paired samples of serum from 200 children in the United States and 1,165 children from Upper Volta in West Africa and from two Pacific islands (Guam and Tol, Truk Islands) were tested for hepatitis B antigen by radio-immunoassay and for the homologous antibody by passive haemagglutination. The antigen was not detected in any of 100 normal children in the United States but it was found in 5% of 100 children resident in institutions in that country. The antigen was found in 2–10.9% of sera from normal children from overseas. Hepatitis B antibody was not detected in normal American children, but it was present in 9% of American children in institutions, 3% in Guam, 20.3% in Tol and 7% in Upper Volta.

Gerety *et al.* calculated the 'per cent. carriers' according to the formula: antigen carriers/infected group \times 100, where the infected group is defined as children with hepatitis B antigen or antibody, or both. The figures obtained were nil for normal American children, 35.7% for children in institutions, 40% for children in Guam, 35.2% for children in Tol and 28.6% in Upper Volta. The respective figure for American adults, calculated from published reports, is 1.8–3.5%.

Several different mechanisms may predispose to persistent carriage of hepatitis B antigen. It has been suggested that the establishment of a complete or at least a partial immunological tolerance to this antigen is the most likely explanation. A relative immune deficiency, associated with slow maturation of cellular immunity in newborn infants, is one possibility. This mechanism may play an important part in carriers resulting from vertical transmission of hepatitis B virus (*Nature*, **249**, 105; 1974). Gerety and associates (*loc. cit.*) found, however, that the risk

Channelled scablands of Washington

THIS picture shows part of the 40,000 km² 'channelled scablands' of eastern Washington, and is from a new booklet produced by the US Geological Survey (*The Channelled Scablands of Eastern Washington*, US Government Printing Office, Washington DC, 1974, 65c). The geological events leading to the formation of this unique landscape began during the Miocene with the extrusion of up to 3,000 m of basalt lava flows which later tilted and warped and acquired a

30–60 m cover of loess. Then beginning about 100,000 years ago ice lobes from the northern hemisphere glaciation encroached on the lava field, damming rivers with glacial ice and debris and forming large lakes. Finally, 10,000–20,000 years ago the dam containing the largest lake broke and more than 2,000 km³ of water and debris were released within a day or two, carving the surface as observed today.

P.J.S.

of becoming an antigen carrier seemed to be uniform among children ranging in age from 1 month to 15 years. They considered that factors of exposure such as the route and amount of virus may contribute to the disparate chronic infection rates between children and adults. For example, means of transmission of low dose of virus in children, other than by direct skin penetration, might influence the severity of the infection and the immune response, favouring the development of the carrier state, but the available information is incomplete. An intensive immune response may be essential for the elimination of the virus and the prevention of the establishment of an equilibrium between the host and the infecting agent. There are reports in the literature which suggest that adults seem to become carriers more frequently after a mild attack of hepatitis (Barker and Murrey, *J. Am. med. Ass.*, **216**, 1970; 1971; Aach *et al.*, *Proc. natn. Acad. Sci. U.S.A.*, **68**, 1656; 1971; Gocke, *J. Am. med. Ass.*, **219**, 1165; 1972). And, in general, children experience a milder disease with many sub-clinical infections.

Carriage of hepatitis B antigen has been consistently reported to be more

frequent in males than in females and evidence has been obtained which indicated sex as an independent primary variable factor responsible for a higher prevalence of the antigen in males than in females. Washburn and colleagues (*Pediatrics*, **35**, 57; 1965) studied the sex difference in susceptibility to a number of infections. A significant preponderance of males was found and this was most marked in infancy. The sex difference in susceptibility was postulated to be consistent with a gene locus on the X chromosome which is involved in the synthesis of immunoglobulins. Small differences in the amounts or rates of synthesis of antibody might be responsible for a slightly greater susceptibility to infection among members of one sex. Gerety and his colleagues found that the likelihood of the development of the carrier state in the groups of children they studied did not seem to correlate with the sex or with the geographical origin of the children or with the subtype of hepatitis B virus. What the results did show clearly was that children became persistent carriers more frequently after infection with hepatitis B virus than adults in the United States.

Identification of HO₂

from our Chemical Physics Correspondent

Most chemists and chemical engineers would feel that HO₂ is one of the commoner and better known of the gas phase free radicals which are common intermediates in so many reactions. Hydrocarbon combustion, both in heating plants and in motor engines, is a major process in which HO₂ is a significant intermediate and many important kinetic rate constants are concerned with its creation and subsequent destruction. However clear cut, physical identification and study have proved remarkably difficult. Even the powerful tools of photolysis and of matrix isolation have found HO₂ to be a slippery customer and ultraviolet, infrared and electron resonance spectra of only indifferent quality and resolution have been obtained. More informative gas phase spectroscopy has been, hitherto, remarkably unsuccessful and this is not for want of much hard and difficult work.

Now, however, the powerful team of Radford, Evenson and Howard (*J. Chem. Phys.*, **60**, 3178; 1974) has obtained a remarkably clear spectrum which must be attributed to HO₂, unless even now this radical has sent a Doppelgänger to confuse us. The authors believe it relates to HO₂ but the evidence is indirect. The spectrum appears from more than twenty likely reaction mixtures including O₂+C₂H₄, O₂+C₂H₂, H₂O₂+F, H+O₂ and from discharges in water vapour. The spectrum near 130 cm⁻¹ vanishes when the H is exchanged for D or ¹⁸O by ¹⁸O, but it remains unaltered when ¹³C is used instead of ¹²C in the reagents. The species is certainly paramagnetic, probably uncharged and seems to contain an odd number of nuclei like H with a spin of 1/2. The evidence is certainly sufficient to convince most readers, including your correspondent, but is not quite at the level of absence of all reasonable doubt that would be required by a murder jury. A particularly important aspect of the present spectrum is its availability as a monitor during the maximisation of the concentration of the concentration and life-time of the HO₂ in future experiments. This will be of interest to research workers in combustion and further details of the rotational spectrum will be eagerly awaited by astrophysicists who would seek HO₂ in interstellar gas by means of its microwave spectrum.

The spectrum was observed with a powerful technique which uses the absorption of the H₂O and D₂O laser lines near 119, 126 and 139 cm⁻¹ (84, 79 and 72 μm). Since these lines do not coincide perfectly with the HO₂ absorption, the latter is modified by a magnetic field up to 2 T (20 k gauss) using the Zeeman effect. This technique, called laser magnetic resonance, is sensitive only to paramagnetic species, so that the many dia-

magnetic species in the reaction stream do not interfere. Using magnetic field modulation and a phase sensitive detection system about twenty lines are easily detected with each laser frequency using separately the laser electric field parallel and perpendicular to the magnetic field, a change which modifies the selection rule on the Zeeman sublevels. Indeed the signal to noise ratio is such that the doublet nature of the lines, due to the proton magnetic moment coupling with the unpaired electron, is clearly resolved with a separation of 1 mT (10 gauss). The radical is close to a prolate symmetric top and has $A \sim 19.4$ cm⁻¹ and $(B+C)/2 \sim 1.26$ cm⁻¹. The rotational quantum numbers N and K provide useful state labels and the transition near 139 cm⁻¹ is assigned to the $K \leftarrow 2$ and $N \leftarrow 18$ transition although $N \leftarrow 19$ is not completely excluded by the evidence. There is a zero field splitting between the $J=N+1/2$ and the $J=N-1/2$ states which is 0.605 cm⁻¹ for $K=2$ and 1.139 cm⁻¹ for the $K=3$ level. The transitions are for the $J=N+1/2$ states.

Vegetation disturbance in arctic tundra

from Peter D. Moore
Plant Ecology Correspondent

THE slow recovery rate of alpine tundra following the disturbance of surface vegetation (see *Nature*, **249**, 690; 1974) is causing concern. A similar, but more complex problem confronts conservationists in arctic tundra regions, where the existence of permafrost within the soil means that thermal equilibrium is a critical factor in determining ecosystem stability.

Dingman and Koutz (*Arctic Alpine Res.*, **6**, 37; 1974) have studied the pattern of frozen subsoil distribution in a region of central Alaska where permafrost is discontinuous. They were concerned in particular with microtopography and the way in which such factors as aspect can influence the net potential radiation input and hence the depth of the active layer (seasonal thaw zone). A rather rough, non-linear correlation emerges between their potential insolation index and active layer depth, and their figures suggest that permafrost occurs where the average annual solar radiation falls below 265 cal cm⁻² d⁻¹.

The anomalous points on the graphs of Dingman and Koutz, which distort some of their regressions, frequently correspond to locations of unusual vegetation type, such as forest cover or exceptionally thick moss hummocks. Evidently the influence of surface vegetation on ecosystem energy balance, particularly on albedo and on latent

heat losses associated with transpiration, must be taken into account.

This aspect has been studied by Haag and Bliss (*J. appl. Ecol.*, **11**, 355; 1974) who have conducted experiments to test the effect of vegetation disturbance upon tundra energy budgets. Damage to surface vegetation and peat on areas used as roads during the winter months resulted in increased surface moisture and therefore in considerable albedo changes (6.1%, compared with 15.2% in control sites); in consequence there was an increase in net radiation input in the road site. In addition, the compaction or disturbance of the surface peat layer led to an increase in thermal diffusivity, as a result of which higher soil temperatures were recorded during the day even at a depth of 50 cm in the road profile. Latent heat losses were greater in the control site, especially in the growing season when actively transpiring vegetation was fully developed and deeper reserves of water were being tapped.

One of the important conclusions of this work is that the use of tundra as a winter road alters the soil thermal régime, resulting in a deeper active layer in summer (about 56 cm compared with 36 cm in control). Similarly other types of disturbance such as fire and oil spills produced deeper active layers (46 cm and 42 cm respectively). Such conditions are conducive to surface instability and erosion. A possible solution to the problem would be the reseeded of disturbed areas to assist surface healing.

Wein and MacLean (*Can. J. Bot.*, **51**, 2509; 1973) investigated the potential of *Eriophorum vaginatum* (cotton sedge) as a recolonist of bare peat and mineral soil and came to the conclusion that the species could be of particular value where mineral soils were exposed and where the soil is permanently saturated. This is precisely the set of conditions found on parts of the winter roads. The seeds germinated best at 25–30° C and had no dormancy problems; when sown in July they were found to be strong enough to withstand the subsequent winter.

Re seeding experiments in disturbed tundra areas are now being conducted, but the initial data of Haag and Bliss suggest that the development of a vegetation cover will be slow; only 20–50% surface cover has been attained after three seasons' growth. Albedo has risen in the reseeded plots, leading to a decrease in the net radiation input, but active layer depth has decreased by only 2 cm (from 52 cm to 50 cm). It would seem that the loss of thermal insulation provided by a peat cover is even more vital for the maintenance of a shallow active layer than is high albedo. The redevelopment of a peat blanket will obviously take a very long time.

Seven years of L-dopa therapy

by Miranda Robertson

NOMINALLY, the symposium held on June 28 by the Parkinson's Disease Society was to mark the fact that it is now 150 years since the death of James Parkinson. What was most clearly reflected in its content, however, was that it is now seven years since the advent of L-dopa therapy, which seemed at one time to promise freedom from parkinsonism but has turned out merely to suspend sentence. This has left pharmacologists to try and find out what to do next and clinicians with the problem of what best to do in the meantime; and that, apart from an historical excursion by J. D. Parkes (Institute of Psychiatry, London), was what the symposium was about.

There has been no radical change in the therapeutic approach to parkinsonism since Charcot first used anticholinergic drugs a century ago. The aim is still to redress the balance between cholinergic and dopaminergic agonists in the basal ganglia, but with the emphasis on supplying the missing dopamine rather than blocking acetylcholine reception. K. Fuxe (Karolinska Institute, Stockholm) favoured ergot derivatives and in particular 2-bromo-alpha-ergocryptine (CB154) as future alternatives to dopamine derived from L-dopa. The advantages of these dopaminergic agonists over L-dopa would be that they act directly on the dopamine receptor without having to be converted to the active form by enzymes which may be deficient as a result of the same degenerative process that produces the dopamine deficiency. Fuxe, who has tried CB154 on rats with nigro-striatal lesions, is optimistic about the compound whose effects, though weaker than those of L-dopa, are more prolonged. His hope, however, that CB154 might also be free of some of its side effects is not substantiated by preliminary clinical trials, reported by D. Calne (Hammersmith Hospital, London). Functional improvement was assessed blind at between 9% and 18% on average for 20 patients on the drug, the degree of improvement being positively correlated with the severity of the disability. But adverse reactions seemed to parallel those seen with L-dopa therapy.

Amplification of post-synaptic effects through the adenylyl cyclase system, which is also under investigation at the Karolinska Institute, may conceivably help with the separation of therapeutic from side effects, although as C. D. Marsden (King's College Hospital, London) pointed out, it is not clear how different the receptors mediating the one are from those mediating the other. In Fuxe's rat model, however,

theophylline (which inhibits phosphodiesterase and thus increases the concentration of cyclic AMP) does seem to increase activity in the denervated striatal neurones, and he believes that it may be possible to use the drug to potentiate the effects of CB154.

All this, however, assumes a functional post-synaptic receptor mechanism, and as M. Sandler (Queen Charlotte's Hospital, London) pointed out, receptor pathology is by no means ruled out. Sandler, who has long held that the dopamine replacement theory of L-dopa therapy is an oversimplification, devoted much of his talk to hauling skeletons out of cupboards. One of them is ignorance of the exact cause of Parkinson's disease, and of the contribution of deficiencies in chemicals other than dopamine to the syndrome. The other is the failure to explain either how L-dopa works or why it stops working. Neither the disease nor dopa metabolism, in short, is understood.

What seems to be missing is a really good animal model for parkinsonism. Sandler stressed that drugs do not always have the same effect on lesioned rats as they do on parkinsonian humans. This is hardly surprising if only because the parkinsonian lesion is most unlikely to be as simple as the destruction of the nigro-striatal pathway, besides which, autopsy brains of parkinsonian patients show evidence (quoted by M. Yahr, Mount Sinai School of Medicine) of continuing degeneration under L-dopa therapy; whereas the surgical lesion does not evolve.

There is also the question of the effect of prolonged administration of drugs. Clinicians repeatedly brought up the need at the very least for studies on the effects of anti-parkinsonian agents over long periods of time. Progressive disease may explain why parkinsonism in due course overcomes L-dopa therapy; but what is the explanation of the simultaneous increase in the dyskinetic side effects of the drug?

Some recent work of H. Klawans (University of Chicago) suggests that the answer may lie in the post-synaptic dopamine receptors. He used amphetamine to stimulate the dopamine receptors of guinea pigs to the point at which the drug produced stereotyped movements, and found that after regular treatment over a period of time, the movements could be elicited not only by progressively lower doses of amphetamine but also by the dopaminergic agonist apomorphine.

The meeting ended with a review lecture by A. Carlson (University of Goteborg), whose efforts in establishing dopamine as a neurotransmitter in the late 1950s helped to make possible the introduction of dopaminergic antagonists in the treatment of parkinsonism.

An amoeba becomes a flagellate

from F. E. G. Cox
Parasitology Correspondent

PARASITOLOGISTS are tidy people and like to know how parasites should be classified. The understanding of the correct taxonomic status of a parasite is more than the provision of a handy slot in which to file information; it is the basis of an understanding of the biology of the organism and a point to which related organisms can be referred. From such a reference point stems a knowledge of basic biochemistry, physiology and epidemiology and on these studies the control of the parasite can be based. Parasites, particularly protozoa, are often very specialised and it is not always easy to see their basic structures with the light microscope. During the past decade, however, the electron microscope has been used to solve several taxonomic problems. Partially as a result of such studies the piroplasms and *Toxoplasma* have taken their rightful position within the sporozoan class Coccidia, and the number of discrete taxonomic groups containing a few parasites of uncertain taxonomic position has been diminished.

One of the outstanding taxonomic problems is concerned with an amoeba, *Dientamoeba fragilis*, which lives in the gut of man. It has long been recognised that this binucleate amoeba could be a flagellate but absolute proof has been lacking. Two independent papers in the *Journal of Protozoology* have now supplied this proof. Honigberg and his colleagues (Camp, Mattern and Honigberg, *J. Protozool.*, **21**, 69; 1974) now report that the fine structure of *Dientamoeba* places it among the trichomonad flagellates and this conclusion is also reached by Dwyer (*ibid.*, 139) using immunoelectrophoretic methods to analyse the antigens of *Trichomonas*, *Dientamoeba*, *Histomonas* and *Entamoeba*. This latter work is a culmination of Dwyer's earlier immunological studies on these parasites (*ibid.*, **19**, 316 and 326; 1972). All the evidence now points to common structures and common antigens linking *Dientamoeba* with the flagellates *Trichomonas* and *Histomonas* and there is a clear evolutionary sequence in which the number of flagella are reduced in *Histomonas* and disappear altogether in *Dientamoeba*. Honigberg suggests a revised classification of the Order Trichomonadida in which *Dientamoeba* is placed in the same family as *Histomonas* and this is likely to be generally accepted by protozoologists and parasitologists.

The implications of these studies lie in an understanding of the mode of transmission of parasitic members of the order Trichomonadida, Protective

cysts are unknown in these forms and the parasites have had to evolve unusual ways to ensure transmission. *Histomonas meleagridis*, the causative organism of blackhead in poultry, enters the egg of the nematode *Heterakis gallinarum* (Lee, *Parasitology*, **59**, 877; 1969) and there is abundant evidence to suggest that *Dientamoeba fragilis* of man uses the nematode *Enterobius vermicularis* (Ockert, *J. Hyg. Epidem. Microbiol. Immunol.*, **16**, 213 and 222; 1972; *Abstracts 4th Int. Cong. Protozool.*, Clermont-Ferrand, 1973). As very little is known about the affinities or the transmission of the three species of *Trichomonas* in man there may be some surprises for those who suggest infection as a result of direct contamination.

Structure of nuclear single-particle states

from Peter E. Hodgson
Nuclear Theory Correspondent

MANY features of nuclear structure can be understood by considering the individual motions of the constituent nucleons. For most of the time they move on independent orbits, and occasionally collide with each other. The energies and quantum numbers of these orbits can be determined by reactions that remove a nucleon from a nucleus or add one to it.

The single-particle states near the Fermi surface—those with the highest energies—can be most easily studied by one-nucleon transfer reactions like the (d, p) stripping reaction. Deeper states can best be studied by nucleon knock-out reactions like (p, 2p).

Many studies of single-particle states have now been made, and their systematic behaviour from one nucleus to another is becoming clearer. It is found that most states are split into a number of fragments by the residual interactions that are not taken into account in the simple shell model. Thus instead of a single state several states of the same structure and quantum numbers are spread over one or two MeV of energy. The energy of the state, however, can still be defined as the centroid of the fragments, weighted by their spectroscopic factors.

A very important question is then whether all the fragments of a particular state have been found, for if some fragments far away from the main strength have been missed this could produce serious errors in the centroid energies. It is not easy to detect small fragments experimentally, so other methods must be tried.

If one could rely on the theory of the interaction removing the nucleon there would be no difficulty, for one could simply calculate the sum of the

spectroscopic factors and see if they added up to unity, the value corresponding to a pure single-particle state. Unfortunately, even in favourable circumstances the distorted wave theories cannot be relied upon to better them about 10–20%, and one is concerned with the loss of small fragments constituting around 5–10% of the total strength.

Another approach is to use a sum rule with all the single-particle states in a particular nucleus. Koltun (*Phys. Rev. Lett.*, **28**, 182; 1972) has shown that provided only two-body forces are present in the nucleus, the total energy of the nucleus may be expressed as a sum of the kinetic and removal energies of the constituent nucleons.

$$E = \frac{1}{2} \sum_i (T_i + E_{iR})$$

The total energy E is known accurately from the nuclear masses, and the kinetic energies T_i can be calculated quite easily from a simple nuclear model. The removal energies E_{iR} are obtained directly from the centroid energies. The sum rule thus provides a sensitive test of the completeness of the sets of fragments assigned to each single-particle state. It does, however, refer to all the nucleons, so the set of single-particle states is tested as a whole, and not individually.

Since the most complete sets of data are available for the proton single-particle states, it is useful to split the above sum rule into the corresponding relations for protons and neutrons separately. Thus the mean binding energy per proton becomes

$$E/Z = \frac{1}{2} \{ \langle T \rangle + \langle E_R \rangle - m_p \langle T \rangle / M_{A-1} \}$$

where the angular brackets denote averages only over the proton single-particle states. The extra term is a recoil correction that must be included in accurate work.

This sum rule has recently been tested by a group at Saclay (Bernheim *et al.*, *Phys. Rev. Lett.*, **32**, 898; 1974) using the (e, e'p) reaction at 497 MeV. This reaction is preferable to the (p, 2p) reaction because the electrons are less likely than protons to interact with other nucleons before or after their main quasi-elastic interaction with one of the nuclear protons. For the same reason the cross section for the knockout reaction is reduced, but improvements in the experimental apparatus have so increased the incident intensity that it is possible to obtain significant results in a practicable time.

The single-particle states are detected by measuring the energies of the inelastically-scattered electron and of the ejected proton. Application of the conservation laws then gives the energy required to remove the proton, which is just the required energy of the

single-particle state. If the distribution of this energy is plotted for a large number of knockout events the single-particle states are evident as peaks, and the angular distributions of these peaks enable the quantum numbers of the corresponding single-particle states to be found.

The results for $^{12}\text{C}(e, e'p)$ are shown in the figure, and clearly show the peaks corresponding to proton removal from the 1s and 1p states. The widths of these peaks are due partly to the inaccuracies in the measurements and partly to the energy spread of the fragments which are not resolved individually.

These data were used to test the proton sum rule. After correcting for distortion of the outgoing proton waves in the nuclear field they found -4.0 ± 0.5 MeV for the mean binding energy per proton, compared with the value -6.93 MeV obtained from the nuclear masses with Coulomb corrections. This is a very significant discrepancy. One possible explanation is that there are some small fragments many MeV away from the main peaks. Bernheim *et al.* estimate that 5% of the strength associated with average separation energies of 150 MeV would be sufficient to account for the discrepancy. The rate of fall-off of the 1s peak with increasing energy is such, however, that if it continues to higher energies this explanation is very unlikely. On the other hand if there is a discontinuity in the fall-off this constitutes a new phenomenon requiring explanation.

Another possible explanation of the discrepancy is the presence of three-body forces, whose absence was assumed in deriving the sum rule. In order to account for the data, the contribution of three-body forces to the binding energy per proton would have to be $\langle H_3 \rangle / Z = 5.9$ MeV, which at present seems unlikely. If this possibility is confirmed, it would be of

Spectrum of the 'missing energy' in the reaction $^{12}\text{C}(e, e'p)$ with (—) and without (---) radiative corrections. The 'missing energy' is equivalent to the energy required to remove a proton from ^{12}C , and the peaks at about 16 and 35–40 MeV correspond to removal from the 1p and 1s states respectively.

great importance for the study of nuclear structure. It is also possible that the discrepancy would be reduced or even eliminated by a full relativistic analysis, but this has not yet been done.

Sun-shuttling lizards

from our *Animal Ecology Correspondent*

LIZARDS are distinctive by their relative absence from temperate forests. This situation, on the face of it, seems anomalous in view of the great abundance of insect prey species in this sort of habitat. Huey (*Science*, **184**, 1001; 1974) now points out that this anomaly may be resolved by considering the ecological difficulties encountered by poikilothermic carnivores.

Unable to thermoregulate physiologically, most lizards move about from sunshine to shade or modify their body posture to alter surface areas exposed to heat sources and thus thermoregulate behaviourally (Cowles and Bogert, *Bull. Am. Mus. nat. Hist.*, **83**, 261; 1944; Heath, *Univ. Calif. Publ. Zool.*, **64**, 97; 1965). Their thermal strategy can be described as heliothermy. It is theoretically possible to predict the amount of behavioural thermoregulation that would maximise net profits by calculating the 'costs' of a physical movement into or out of sunshine as against the 'gain' involved in the attainment and maintenance of a specific body temperature. In Huey's study on *Anolis cristatellus* in Puerto Rico the energetic cost of physical movement from shade into sunshine was estimated by measuring the shortest practicable distance from a perch in the shade to one in the sunshine. Anoles occupy a variety of habitats. Huey chose to study two adjacent populations, one in a shaded forest and the other in an open meadowland. If a tree or other perch was totally shaded and offered no sunlit patches, this fact was noted. Many more lizards in the forest were unable to reach full sun without changing perches (which usually meant changing trees) than were those in the meadow. Furthermore, those lizards in the forest that could reach the sunshine were significantly further from it than were those in the open. Thus there seemed little doubt that the energetic 'cost' of heliotactic thermoregulation was far higher in the forest population.

During the early morning the cloacal temperature of anoles in the forest increased significantly slower than that of meadow lizards and was strongly correlated with ambient air temperature. Such a strong relation did not exist between lizards living in the open and the surrounding air; body temperature of lizards in the open fluctuated by only 1.6° C during the day as compared with 4.9° C in the forest.

The interpretation of these observations is that behavioural thermoregulation occurs only where sun and shade conditions are juxtaposed. Where 'costs' are high, as in the three-dimensional environment of the forest, anoles are passive to ambient conditions. Under these conditions the rewards of sun-shuttling are insufficient and this is reflected in very low population densities. What is the evolutionary significance of this exploitative strategy?

A. cristatellus is a remarkable reptile in having such a plastic ecology. The genus is known for its ability to colonise islands *de novo* as well as to form sympatric species on islands already colonised (Williams, *Q. Rev. Biol.*, **44**, 345; 1969), and its degree of thermal tolerance possibly accounts for its widespread success in the Caribbean. Those populations of *A. cristatellus* that occupy open habitats have an energy budget from which reproduction can have a larger share than is possible in forest populations. Although lizards in the two habitats are indistinguishable in terms of dewlap colour, snout-vent length or midbody scale rows, and do not differ with respect to preferred body temperature in a laboratory gradient, it would seem likely that their populations are in the process of active divergence. Perhaps sun-shuttling is the key to two questions: first, the absence of lizards in forests; and second, the complexity of *Anolis* speciation.

Magnetospheres of Earth and Jupiter

from N. A. Heard and A. R. L. Tatnell

THE tragic death of Neil Brice earlier this year in an air crash over the Pacific led to the renaming of the symposium in Frascati (May 28–31) on the magnetospheres of Earth and Jupiter, the Neil Brice Memorial Symposium. After V. Formisano (Spazio Plasma Laboratory, Frascati) had opened the meeting, C. Kennel (University of California) described the valuable contribution of Neil Brice to the study of the Earth's magnetosphere.

The symposium fell naturally into two parts. In the first half the Earth's magnetosphere was reviewed and results from several satellites were presented. K. Schindler (Ruhr University, Bochum) and V. Vasylinas (Massachusetts Institute of Technology) presented theoretical calculations based on models of the magnetosphere; some attempt was made to extend the model of the Earth's magnetosphere to that of Jupiter.

It has been known for some time that Jupiter is a very intense planetary radio source but, as D. Gurnett (University of Iowa) showed, the Earth is not to be outdone in this respect. Imp-6 and 8

satellites have revealed that the Earth is a comparable radio source and in the frequency range from 50 kHz to 500 kHz, at peak intensity, the total power emitted is about 10^9 W. This radio emission is associated with discrete auroral arcs and seems to originate from altitudes of about 2,000 km. It was suggested that a satellite at this altitude might provide some interesting results.

As R. W. Fredericks (TRW Systems, California) pointed out the value of studies of wave-particle interactions to the understanding of the Earth's magnetospheric processes; it was generally agreed that similar studies of the wave-particle interactions in Jupiter's magnetosphere are essential.

Motion of the Earth's bow shock—the shock caused by the supersonic solar wind impinging on the Earth's magnetic field—was discussed by several speakers. The causes of shock motion are not understood but, from data from Heos 1, Formisano and G. Mastrantonio (Frascati) showed that a satellite is likely to encounter the bow shock in motion if tangential discontinuities are the main cause of motion.

E. J. Smith (Jet Propulsion Laboratory, California) confirmed that the outer boundary of Jupiter's magnetosphere fluctuates considerably, a possibility mentioned by several speakers. The vector helium magnetometer results have revealed that the magnetopause is crossed twice on the inbound pass and a number of times on the outbound pass. An interesting feature of Jupiter's magnetic dipole field is that it is directed opposite to that of the Earth. This dipole field is inclined 15° to the rotation axis and offset about $0.1R_J$ north of the equatorial plane and about $0.2R_J$ towards longitude 170°. From this estimated dipole moment the surface field is between 2.3 and 11.7 gauss compared with the Earth's field of between 0.3 and 0.6 gauss. The dipole approximation for Jupiter is even less valid than in the case for Earth, because of the considerable contribution from current sheets around the planet. Pioneer 10 has also confirmed the presence of helium on Jupiter and the existence of an internal energy source in the planet because the excess radiation is 2 to $2.5 \times$ the solar input.

The role of the Galilean moons is still uncertain but, as several speakers showed, Io in particular seems to influence the particle flux considerably. Io is about the same size as Earth's moon and occultation experiments have shown that it has an ionosphere and a surface pressure of 10^{-6} bar.

•The fly-by of a planet obviously leaves a number of unanswered questions and all speakers emphasised the difficulty in distinguishing between spatial and temporal variations.

Health costs associated with the mining, transport and combustion of coal in the steam-electric industry

L. A. Sagan

Palo Alto Medical Clinic, Palo Alto, California 94301

By assigning an arbitrary cost to a human life, Dr Sagan arrives at rough estimates of the health costs associated with power generation. The costs of miners' accidents and diseases are shown to be heavy compared with those of air pollution.

CHOICE between energy sources rarely takes into account factors other than the market value of the commodities^{1,2}. The costs of such decisions to society in general are rarely considered. Some of these costs are environmental: for example, disposal of industrial waste has often been free. Others involve the health, both of the general population³ and of the persons employed in the industry of interest. In my recent study of the nuclear fuel cycle⁴ I showed that the health effects incurred by occupational personnel are far greater than those suffered by the public.

In this study I evaluate the health costs of generating electricity from the combustion of coal. The health costs of coal production and combustion should be considered in energy planning, but it would be presumptuous to imply that choices among alternate fuels will be made solely on the basis of health. Even so, such quantitative data as are available, as well as an understanding of the deficiencies of the data, should be available to planners and decision makers.

I decided to consider the use of coal for the generation of electricity for the following reasons. Although energy demands in the United States are generally doubling every 14 yr, demand for electricity is now doubling every 7 yr. Although nuclear fuel is expected to increase its share of electrical generation to 66% by the year 2000, coal production for steam generation will continue to increase (Table 1).

It is difficult to consider together such diverse health effects as accidental death and injury, and chronic disease caused by industrial chemicals, dusts and gases. The latter are elusive, and their existence and magnitude is difficult to demonstrate. The technique I adopted was the assignment of dollar losses associated with disability and death. This requires an arbitrary assignment of a cost per human life. The figure I have chosen is \$300,000 which is the multiple of an assumed productive value of \$50 d⁻¹ and a loss for accidental death of 6,000 working days as suggested by the American National Standards Institute⁵. No attempt is made to put this estimate on an annual basis by future discounting. I must emphasise that this is not an attempt to make moral judgment about the value of life. Such a valuation of life is implicit in decisions concerning

health and safety expenditures. In a study for the Office of Science and Technology⁶, a life value of \$140,000 was assumed with which to measure the cost effectiveness of automobile safety features. This was arrived at simply by multiplying average American per capita income (\$3,786) by the average age of those who died in automobile accidents (36.9 yr). It is also of interest that in a recent analysis of risks and benefits of United States technology, C. Starr (personal communication) has found that the implicit value of life in public acceptance of technology is \$300,000.

My evaluation is limited to effects which investigators have tried to quantify. In general, I have adopted pessimistic assumptions regarding health hazards in order to assess worst possible effects rather than to ignore effects for which there may be some evidence but not demonstrated proof. For example, the possibility of threshold levels of toxicity are ignored in favour of the assumption of the same proportionate effect at low levels of exposure as found at higher levels. This assumption is often made, particularly for radiation effects, but has recently been criticised as being at variance with the available biological evidence⁷. Health costs are evaluated in relation to measures of true or real value rather than in terms of out of pocket expenditures since these health costs have rarely been paid by the industry responsible for the injuries. A cost of \$50 d⁻¹ is assessed for lost time due to accident, and an equal amount for medical costs incurred. This latter assumption is based on an estimate of medical costs of all accidental injuries⁸.

So I have estimated the health costs of the 180 GW generated by coal-fired power stations in the United States. Those costs are then reduced by a factor of 180, to represent the equivalent of a single 1,000 MW (electric) plant which is the size of a modern plant supplying a city of 1 million people.

For a 1,000 MWe electrical generating plant of modern design, about 2 million tons per year of coal are required, assuming a heat efficiency of 8,500 BTU per KW h, a 67% load factor and the use of a medium grade bituminous coal of 12,000 BTU per pound. In 1970, by the Census of Mineral Industries Report, 140,000 persons were employed in production of bituminous and lignite coals⁹. Production was 3,350 tons coal per employee, so to supply a 1,000 MWe plant for one year with coal would require the labour of 600 persons.

Morbidity and mortality

In 1969 the underground coal mining accident frequency rate was the highest among all industries—nearly 32 disabling injuries per million man hours compared to the average for all industries of only about eight per million man hours¹⁰. As productivity has increased with increasing mechanisation, the risk of coal mining, as measured in fatalities per million tons mined has fallen, but coal mining still remains more than twice as hazardous as metal mining and almost three times as hazardous as non-metal mining. In the five years 1966–1970, 966 officially reported underground miners lost their lives, an average of about 200 men annually. Although surface or strip

Table 1 Predicted use of fossil fuels

	Total energy ($\times 10^{15}$ BTU)	Electricity ($\times 10^{12}$ KW h)	Fossil Fuels for electricity ($\times 10^{15}$ BYU)
1970	69	1.5	14
1985	133	4.5	20
2000	191	9.0	24

mining is considerably less hazardous than underground mining, there were also 31 fatal accidents in surface mining in 1969 and 33 in 1970, the total yearly average thus being approximately 230 men. In 1970, 48.3% of coal was mined from the surface and of this 75% was used by electric utilities. Thirty-nine per cent of deep mined coal was used by electric utilities (US Bureau of Mines, personal communication). Based on these estimates, 103 fatalities can be attributed yearly to the 180,000 MWe of coal generating stations. This is equivalent to slightly more than a half a fatality per 1,000 MW electric steam plant of \$171,000 yr.

In addition to fatal injuries, there were about 2,000 d lost per million man hours worked in 1969 and 1970 (ref. 9). Assuming an 8 hour working day, 1 d in 62.5 is lost to accident. For a 1,000 MW plant requiring the labour of 600 men for its fuel supply, 2,880 d at a cost of \$288,000 would be incurred.

The Bureau of Mines has recently initiated a study of cost-effectiveness of mine safety measures which, if not definitive, at least provides a model for future research and development¹¹. A summary of their recommendations with estimates of cost to the industry together with an estimate of lives saved annually is seen in Table 2. These recommendations are not, however, mutually exclusive nor additive. They also ignore savings that might accrue from increased productivity of new techniques, reduced compensation insurance costs, and reductions in non-fatal accidents.

Pulmonary disease

The Federal Coal Mine Health and Safety Act of 1969 establishes pneumoconiosis as a compensable disease occupationally related to coal mining, based on the observation that both morbidity and mortality from pulmonary disease, regardless of cause, is very significantly increased among coal miners¹². Though the relationship between coal dust inhalation and pulmonary disability remains uncertain¹³⁻¹⁵, some estimate of pulmonary disability from coal mining seems in order.

Since no single objective measure of coal-workers pneumoconiosis relates well with clinical disability, miners' complaints of shortness of breath (dyspnea), are the best measure available. Summing the percentage of men in all age groups with severe dyspnea, the increased frequency of disability is approximately $\frac{1}{2}$ % per year of underground mining experience¹⁴. Most men over 45 with severe dyspnea are disabled, that is, non-working, whereas most men with no or slight dyspnea, both under and over 45, are active. Although this estimate does not fit the data with precision, it does not seem to be an extreme view.

Applying the 0.5% yr formula to the 600 men providing coal to a 1,000 MWe electrical station, 3 men per year would be disabled. Since the Social Security Administration estimates the median age at first application for disability for this disease among miners as 57.1 yr¹⁶, and assuming a normal working life to age 65, then an average of 7.9 yr of working life are lost per man afflicted. Calculating 300 working days per year, each day valued at \$50 d⁻¹, total cost per electrical station per year would be \$355,000.

Table 2 Cost-effectiveness of various improvements in coal mine engineering

Equipment	Annual cost ($\times \$ 10^6$)	Lives saved (yr ⁻¹)
Temporary roof support system	1.62	22
Permanent roof support system	1.5	6
Maintenance and repair	15.2	10
Operator protection on face equipment	1.306	10
Shuttle haulage	40.0	12
Machine loading roof fall accidents	0.045	5
Alternative equipment modifications	(6.611)*	11
Auger-type continuous mining accidents	0.150	6
Performance of miscellaneous hand operations—roof scaling	0.180	8

Total	207.8	23.8		391.1	100.0

Source: ref. 25.

These estimates are based on experience with technology and regulatory standards for dust control which are now replaced by newer mining conditions. But because those characteristics of coal dust which produce pulmonary disease are unknown, there can be no confidence that current dust control standards and procedures will be effective in reducing disease. Furthermore, modern coal mining equipment tends to create more dust, not less.

The Bureau of Labor Statistics does not list accident rates for steam plant operation as a separate category. Information is available, however, from the Tennessee Valley Authority's Colbert and Gallatin plants (personal communication) which both approximate the 1,000 MW plant which serves as my model. Averaging the experience for 1967-71, 6.65×10^6 man-hours were worked annually at each plant with 388.5 d lost because of accidents. There were no fatalities.

Transport of coal

At present 2,300 people are killed annually in the United States by railroad trains, and more than 20,000 persons injured, mostly at grade crossings¹⁷. There were 27,015,000 carloads of freight hauled by railroads in 1970 and 5,296,000 of these were coal. Since half of the coal consumed in the country is destined for steam stations, it can be calculated that about one tenth of all railroad cars are hauling coal to electrical generating plants. If that assumption is correct, then about 230 people are now being killed annually and 2,000 persons injured from transport needs for electrical generation from coal. Since this generation capacity represents the equivalent of approximately 180 stations of 10³ MWe each, 1.3 deaths would occur for each plant. In the absence of any data on the magnitude of disability associated with non-fatal accidents, no charge can reliably be assessed for these losses. Nor is there any charge for other modes of transportation, that is, barge or truck.

Combustion of coal

Goldsmith has reviewed episodes¹⁸ of intense smog which are generally associated with a transient increase in the incidence of death from cardiopulmonary disease among the elderly and chronically ill. This may only reflect a life shortening of a few weeks or months in those already ill, since analysis over several years does not show correlative relationships with air pollution levels. It is more difficult to assess effects on induction of chronic disease from more moderate concentrations of pollutants. Unfortunately, too many other variables have effects which cannot be distinguished from those of the combustion products of fossil fuels (see, for example, ref. 19). There is also the difficulty of identifying the relative effect of each of the air pollutants.

Most attention has focused on sulphur dioxide which can produce acute toxicity in both human and animal populations²⁰. The necessary concentrations are, however, far greater than those found in urban air. Acute smog episodes, such as those of London, 1952 (ref. 2) and Donora, Pennsylvania, 1948 (ref. 22) have produced increased mortality with SO₂ levels which cannot be demonstrated to produce unequivocal human disease.

The earliest published attempt at estimating the cost of health from air pollution is that of Ridker²³ who estimated that 18 to 20% of the approximately \$2 billion in national health costs for respiratory diseases are due to air pollution. Thus the damage to health from air pollution in 1958 was between \$360 and \$400 million.

The Lave-Seskin study³ expands the scope of disease covered by Ridker. In particular they take into account air pollution damages to health in the forms of heart disease and of cancers of the stomach, oesophagus and bladder. Approximately half the lost income and current medical expenses associated with morbidity and mortality from bronchitis are ascribed to air pollution. The coefficient for lung cancer is estimated to be 0.25. In other disease categories air pollution is held responsible for an estimated 15% of the damages associated with non-respiratory lung cancers, 25% of all respiratory diseases and 10% of cardiovascular diseases. These coefficients were estimated by regressions that were run on data from published epidemiological studies.

The total annual reduction in health costs which Lave and Seskin anticipate from a 50% reduction in air pollution is \$2,080 million. Scaling up to 100% implies a total cost of \$4,160 million annually. An Environmental Protection Agency evaluation²⁴ has updated this figure calculated in 1963, to \$6,060 million to account for inflation.

The method of regression analysis as a technique for assessing health effects of air pollutants is not definitive; but in the absence of other data I shall use this value of \$6,060 million for evaluating health costs of coal-combustion products.

Of the total tonnage of United States air pollutants shown in Table 3, coal burned for electrical generation is responsible for approximately 8% (ref. 25). To apply this percentage to the total air pollution health cost of \$6.06 billion would be to treat all pollutants as having equally damaging effects on a weight basis. Walther²⁶ has calculated an 'effect factor' for each pollutant on the basis of its toxicity as reflected by primary air quality standards. The technique is obviously crude, but the health impact of any pollution source can be roughly estimated by multiplying the annual emission of each pollutant by the effect factor. This (Table 3) produces an annual estimate of \$357.5 million for the nation as a whole or approximately \$2 million per 1,000 MW plant. Such an evaluation would clearly be high because of the implicit assumption that all emission sources contribute equally to ground level concentrations, and ignores the fact that the use of high stacks at steam plants very much increases dispersion and therefore reduces ground level concentration.

British studies demonstrate that even in the neighbourhood of a modern 1,000 MW electric plant less than 5% of ground level SO₂ can be attributed to plant emissions. This was equivalent to adding only 0.1 to 0.2 parts per hundred million (p.p.h.m.) SO₂ to average background levels measured at the worst point. At greater distances where population density would usually be greater than in the immediate plant area, ground concentrations of SO₂ contributed by the plant would be in the range of 0.01–0.02 p.p.h.m., which is in the order of 1% of background levels. SO₂ generated by steam plants

cannot be detected beyond 20 mile even under the worst meteorological conditions. Nevertheless, I shall arbitrarily accept the value of 1% of the \$357.5 million cost estimated from the tonnage of pollutants emitted from coal-steam plants. This produces an estimated total cost for the 180,000 MW of coal-generated electric power of \$3.6 million (\$20 thousand per 1,000 MW electric plant).

Wilson has estimated from Norwegian data a damage function for ambient SO₂ levels of 10,000 deaths per million "man-concentrations" (a man concentration is equal to number of persons exposed, multiplied by average exposure to SO₂ in p.p.m. averaged over one week)²⁸. Estimating the population within 20 miles of a steam plant from recent environmental impact statements, it would appear that 400,000 people live within this vicinity. Exposure to 0.02 p.p.h.m. for one year would produce, on the basis of the Wilson estimate, 0.8 death.

Although the evidence relating the health effects of air pollution to its sulphur dioxide content is frail, environmental control efforts focusing on reduction of ambient sulphur dioxide levels have been adopted with little opposition. Techniques for the removal of SO₂ from stack gases are still relatively unproven; however, the US Bureau of Mines estimates that for the technique receiving the greatest interest commercially, lime/limestone scrubbing, costs (including capital charges) are in the range of 1.0 to 0.25 cents per kW h. This system has not yet proved capable of removing more than 30 to 50% of the sulphur dioxide present. At best, stack gas removal systems are not expected to remove more than 75% of the SO₂ present. For most United States coal, this degree of removal would not be sufficient to reach current ambient air standards²⁹. Clarke, Lucas and Ross³⁰ have calculated costs of reducing ground level concentrations from a coal-burning steam plant (Fig. 1). They conclude that stacks are far more economical than sulphur removal systems for reducing ground level concentration.

Adopting the meteorological and cost assumptions³⁰, shown in Fig. 1, and the damage function of Wilson (1 death per 100 man-concentrations) Table 4 was constructed. A population density of 320 persons km⁻² was also assumed producing an expectation of 42 deaths annually with a stack height of 30 m. Intuitively, this result clearly seems unlikely, probably implying a highly inflated risk factor.

With ground level concentrations converted to mortality data, an assumed value of life can be applied to evaluate cost-effectiveness of reducing sulphur dioxide concentrations. The precision of the numbers may give the illusion of precise knowledge which is, in fact, not available.

Accepting the life value used in this study (\$300,000) or even a far smaller one, tall chimneys are clearly cost-effective, whereas sulphur removal processes seem relatively cost-ineffective except in the unlikely case of sources near ground level. This implies that scarce, low-sulphur fuels should be reserved for ground level sources whereas tall stacks should be used for major industrial sources such as steam plants. This conclusion ignores questions of property damage or possible benefits to agriculture from sulphur contamination.

Total human costs of operating a 1,000 MW station are summarised in Table 5. Although these costs are indeed large

Table 4 Cost effectiveness of stacks and sulphur removal in reducing mortality

Chimney height (m)	Capital cost (\$)	Chimney alone		Plus 50% S removal (\$5,000,000)		Plus 75% S removal (\$10,000,000)	
		Annual deaths	Implicit life value* (\$)	Additional lives saved	Implicit life value (\$)	Additional lives saved	Implicit life value (\$)
30	0	42	0	21	238,000	31.5	318,000
70	120,000	23	222	11.5	434,000	17.3	578,000
100	333,000	11	358	5.5	910,000	8.25	1,220,000
120	575,000	4	504	2	2,500,000	3	3,330,000
170	1,600,000	0	1,270	0	infinite	0	infinite

* Implicit life value = total reduction in mortality over 30 yr plant life divided by capital cost.

Fig. 1 Dependence of total pollution on source strength and chimney height. Threshold: $100 \mu\text{g m}^{-3}$; wind speed: 5 m s^{-1} . Source strength of SO_2 (kg s^{-1}) and capitalised cost of its removal: a, 1, \$0; b, 5, \$ 5 million; c, 25, \$ 10 million; d, 125, \$ 15 million.

in human terms, they are small compared to annual revenues generated by such a plant. Assuming a load factor of 67% and sales at 2 cents per kW h, annual revenue from such a plant would be about \$29 million.

Mining of coal is seen to account for approximately 50% of all health costs associated with the generation of electric energy from coal. Strip mining is only about 15% as likely to cause death and probably provides a similar advantage in terms of coal workers' pneumoconiosis. This phenomenon receives little attention from those who are attempting to limit or eliminate surface mining in favour of the far more hazardous

underground mining. Still, opportunities for accident reduction in underground mining which are highly cost-effective seem to be available but are so far unexploited.

On the other hand, air pollution costs seem to be small compared to other health costs of coal-steam plants—less than 5%. Sulphur removal techniques at their present state of development cannot be shown to be cost-effective, particularly in contrast to stacks and other operational control procedures. Because of the greater effectiveness of the latter, regulatory control would rationally relate to ambient air standards where the operating utility could avail itself of cost-effective techniques rather than to effluent standards where the utility must resort to technology which is clearly cost-ineffective. Furthermore, ambient controls are more likely to reduce levels of other pollutants a corresponding amount whereas effluent controls are likely to be specific to SO_2 . Since the health hazard of air pollution from the combustion of coal is not known to be related to SO_2 exclusively, the importance of this effect is obvious.

It may be useful to compare this estimate of health costs with my estimates for a nuclear power plant of equal power rating⁴. Total costs for 10,030 MWe of the current United States nuclear industry were evaluated at \$2,175,520. For a single 1,000 MWe nuclear plant, cost would be \$217,552 or less than 20% of the annual cost of the coal fuel plant. Although there are uncertainties in both estimates, it would seem likely that the nuclear plant is clearly less hazardous than the coal-fired plant. An official Swedish study³¹ comparing nuclear plants with oil fuel plants reached essentially the same conclusion although the spread between the two fuel sources was found to be considerably greater. Lave has reached a similar result³².

These conclusions refer to normal operating conditions and ignore possible differences in accident potential, for which precise data are not available. Recently Starr *et al.*³³ have analysed and compared accident probabilities for nuclear plants and fossil-fuelled generating plants. They conclude that the probability of accidental death from the nuclear plant is smaller than from a similar fossil-fuelled plant.

The greatest weakness in this analysis is the estimate of health costs of air pollution. Ultimately, the most significant estimates will follow establishment of damage functions for each pollutant and the ability to evaluate total human impact of such exposures from known meteorological and chemical behaviour in the environment.

Are BL Lac-type objects nearby black holes?

Stuart L. Shapiro & James L. Elliot

Center for Radiophysics and Space Research, Cornell University, Ithaca, New York 14850

Isolated black holes accreting interstellar gas can account for the salient properties of the BL Lac-type objects. The observed frequency spectra in the visible and infrared, the rapid variations in intensity and polarisation, and the absence of discrete features in the optical spectra are all consequences of the adopted black hole accretion model.

STRITTMATTER *et al.*¹ have discussed the possible existence of an entirely new class of astronomical objects with the following properties: (1) extremely rapid variations in the radio, infrared, and optical intensity; (2) most of the energy is emitted at infrared wavelengths; (3) absence of emission or absorption lines in their optical spectra; and (4) substantial and variable polarisation at optical and radio wavelengths. The prototype and most extensively studied object in this class is the variable star BL Lacertae (VRO42.22.01). Other Lacertids, as members of this class are now known, include OJ287 (VRO20.08.01), ON231 (W COM), ON325 (B2 1215+30) and PKS1514-24 (AP Lib).

Optical and near infrared spectrophotometry of the objects¹⁻⁴ reveal a steepening decline in the flux density from 10^{14} to 10^{15} Hz. The spectral shape, together with the observed rapid variations in intensity and polarisation, indicates that the observed radiation from the Lacertids results from nonthermal processes. The rapid variations further suggest that the emission originates from a very small region ($\leq 10^{17}$ cm). As a consequence of their nonthermal spectra, compactness and variability, these objects have been likened to quasistellar objects. But no redshifts can be measured because of the absence of spectral lines; so their distances remain unknown. Moreover, in the case of BL Lac, the very steep slope of the spectral-energy distribution above $10^{14.5}$ Hz suggests that this object is not a QSO (refs 3, 5).

As an alternative, we wish to point out that isolated black holes accreting interstellar gas can account for the characteristic properties of the Lacertids. The suggestion that these compact nonthermal sources may be massive ($\geq 10^4 M_\odot$) black holes has already been proposed by Pringle *et al.*⁶. Here we discuss the possibility that the BL Lac-type objects are nearby, stellar-mass black holes ($1 M_\odot \leq M \leq 100 M_\odot$) in the galactic disk.

Basic model

The total luminosity and frequency spectrum of radiation emitted by interstellar gas accreting on to a black hole have recently been calculated for spherically symmetric, steady state accretion^{7,8}. In this case, if there is a finely tangled and randomly oriented magnetic field in the interstellar gas, the rapid reconnection of oppositely directed radial field lines promotes an equipartition of magnetic and gravitational energy throughout the infalling plasma, ($B^2/8\pi \approx GM\rho/r$). Synchrotron radiation by relativistic electrons gyrating around the magnetic field lines is the principal radiation mechanism in the gas, resulting in a total observed luminosity

$$L_s \approx 5 \times 10^{30} (T_0/10,000 \text{ K})^{-3} (M/10 M_\odot)^3 (n_0/10 \text{ cm}^{-3})^2 \text{ erg s}^{-1} \quad (1)$$

provided $\beta = (T_0/10,000 \text{ K})^{-3/2} (M/10 M_\odot) (n_0/10 \text{ cm}^{-3}) \ll 10$. Here, n_0 and T_0 are the density and temperature, respectively, of the ambient gas and M is the mass of the black hole. If the black hole is moving supersonically through a uniform medium with a velocity V , the results of the calculations still apply provided we set $kT_0 \approx m_i V^2$, where k is Boltzmann's constant and m_i is the ion mass. The calculated spectral energy distribution falls sharply with frequency throughout the range $v_1 \leq \nu \leq v_2$, where

$$v_2 \approx 7 \times 10^{15} (n_0/10 \text{ cm}^{-3})^{1/2} (T_0/10,000 \text{ K})^{-3/4} \text{ Hz} \quad (2)$$

is the peak synchrotron emission frequency in the region immediately outside of the Schwarzschild radius at $r = 2m$ = $2.95 \times 10^6 (M/10 M_\odot) \text{ cm}$ and

$$v_1 \approx 2 \times 10^{13} (n_0/10 \text{ cm}^{-3})^{40/49} (T_0/10,000 \text{ K})^{60/49} (M/10 M_\odot)^{31/49} \text{ Hz} \quad (3)$$

is the characteristic frequency below which synchrotron radiation is self-absorbed by the gas.

Comparison with observations

The continuous emission spectrum is plotted in Fig. 1 for the accretion of ionised hydrogen with $T_0 = 10,000 \text{ K}$ (corresponding to $V \approx 10 \text{ km s}^{-1}$) on to a single black hole. Emission spectra are shown for various interstellar gas densities and black hole masses and the results are compared with the data plotted by Strittmatter *et al.* for the BL Lac-type objects. Each theoretical curve has been fitted to the observed data for BL Lac at approximately $10 \mu\text{m}$. This corresponds to placing the black hole at a distance.

$$d \simeq 10 \text{ pc } (n_0/10 \text{ cm}^{-3}) (M/10M_\odot)^{3/2} \quad (4)$$

For all curves most of the energy is emitted in the infrared part of the spectrum in agreement with the observed spectra. The theoretical curve computed for $n_0 = 10 \text{ cm}^{-3}$ and $M \simeq 10 M_\odot$ is in reasonable agreement with the observed spectral energy distribution of BL Lac in the visual and infrared to $10 \mu\text{m}$.

Irregular time variations in intensity and polarisation are a natural consequence of an accretion model. Inhomogeneities in the ambient medium as well as instabilities and turbulence associated with the flow will inevitably lead to significant fluctuations in the total emission from the gas. These fluctuations are expected to occur over a variety of time scales. For example, intensity variations may result when the hole moves out of one turbulent cell of interstellar gas and into another⁹. The time scale for such variations is roughly

$$\Delta t_{\text{urb}} \simeq r_c/u_0 \simeq (10 \text{ yr}) (M/10M_\odot) (u_0/10 \text{ km s}^{-1})^{-3} \quad (5)$$

where $r_c = GM/u_0^2 \simeq 5 \times 10^{14} (M/10M_\odot) (u_0/10 \text{ km s}^{-1})^{-2} \text{ cm}$ is the capture radius of the black hole and $u_0 = (a_0^2 + V^2)^{1/2}$, where a_0 is the ambient sound velocity. On shorter time scales magnetic field reconnection, which is believed to be responsible for solar flares (see ref. 10 and references therein) may lead to strong flaring in the luminosity of the accreting gas. In the proposed accretion model the largest scale size associated with magnetic reconnection is roughly r^* , where r^* is the radius at which the frozen-in magnetic field has been sufficiently amplified by the compression of the infalling fluid that $B^{*2}/8\pi \approx GM\rho^*/r^*$. In the zone $r_c \geq r \geq r^*$, lying just above the reconnecting region, the field is frozen in, requiring that $B \simeq B_0(r_c/r)^2$; so the reconnection rate at r^* , is given by

$$\Delta t_{\text{rec}}^* \simeq r^*/v_A^* \simeq (0.01 \Delta t_{\text{urb}}) (B_0/3 \times 10^{-6} \text{ gauss})^2 (n_0/10 \text{ cm}^{-3})^{-1} (u_0/10 \text{ km s}^{-1})^{-2} \quad (6)$$

where v_A^* is the Alfvén speed at r^* and B_0 is the ambient field strength. Magnetic reconnection will occur throughout the region $r^* \geq r \geq 2m$, maintaining an equipartition of magnetic and gravitational energy in the plasma. The longest timescale associated with magnetic flaring is $\Delta t_{\text{mag}} \approx \Delta t_{\text{rec}}^*$ or

$$\Delta t_{\text{mag}} \simeq (0.1 \text{ yr}) (B_0/3 \times 10^{-6} \text{ gauss})^2 (n_0/10 \text{ cm}^{-3})^{-1} (M/10M_\odot) (u_0/10 \text{ km s}^{-1})^{-5} \quad (7)$$

A sudden release of magnetic field energy and magnetic pressure should accompany each flare, causing an enhanced flow of plasma toward the hole and a corresponding burst of luminosity lasting a period Δt_{mag} . Finally, the shortest timescale for luminosity fluctuations is presumably associated with the infall rate (\simeq reconnection rate) near the Schwarzschild radius,

$$\Delta t_{\text{min}} \simeq 2GM/c^3 \simeq (10^{-4} \text{ s}) (M/10M_\odot) \quad (8)$$

The random outbursts lasting ~ 1 month which occur on BL Lac and OJ 287 (refs 11–14, 18) agree with the predicted duration of a magnetic flare, assuming stellar-mass black holes and typical interstellar conditions (see equation (7)). BL Lac also exhibits more gradual luminosity modulations lasting about 10 yr (ref. 12). This long period variability may be associated with inhomogeneities in the interstellar medium in accordance with equation (5). Similar optical variations, occurring on a timescale of years, have been observed in OJ287 (refs 14, 15). Short period variability ($\ll 1$ d) has also been observed for these two objects^{3,14–17}, as would be expected from an accretion model.

A net polarisation of the emitted synchrotron radiation would not occur in the case of spherically symmetric flow and finely tangled and randomly oriented fields. But inhomogeneities in the ambient medium, angular momentum of the gas, instabilities and turbulence may all lead to a highly variable, random net polarisation. The polarisation variations would then be correlated with the flaring activity of the source, a result consistent with the observations^{5,18}.

As shown by the dotted lines of Fig. 1, the synchrotron radiation is strongly self absorbed below $\nu \sim \nu_1$; so another radiation mechanism must be invoked to explain the radio emission from the objects. In the infalling plasma, conditions are favourable for the generation of radio emission through

Fig. 1 The continuous emission spectrum from interstellar gas accreting on to a black hole compared with the observed spectra of the BL Lac-type objects as plotted in Strittmatter *et al.*¹. The gas consists of pure hydrogen with $T_0 = 10,000 \text{ K}$ ($V \approx 10 \text{ km s}^{-1}$); each curve is labelled by the corresponding value of black hole mass M . The dotted lines indicate synchrotron self-absorption. ●, BL Lac; ○, OJ287; □, ON231; △, B2 1215+30; ▲, AP Lib. — · — ·, $n_0 = 1 \text{ cm}^{-3}$; —, $n_0 = 10 \text{ cm}^{-3}$; — — —, $n_0 = 100 \text{ cm}^{-3}$.

coherent processes. Because of steep density and temperature gradients, longitudinal plasma waves and transverse electromagnetic waves will be coupled in the plasma. The possibility then exists for converting some of the electrostatic energy contained in plasma oscillations into radiation, a process which has been proposed as the origin of the enhanced radio emission from active regions on the Sun^{19,20}. The emission from a particular region is confined to the narrow frequency band $\nu_p < \nu < 1.4 \nu_p$, where $\nu_p = (e^2 n / \pi m_p)^{1/2}$ is the plasma frequency. In the model, the radio emission in a given frequency band centred about ν originates from the thin spherical shell of gas at r in which $\nu \simeq \nu(r)$, where

$$\nu_p(r) \simeq 2 \times 10^{10} (2M/r)^{3/4} (n_0/10 \text{ cm}^{-3})^{1/2} (u_0/10 \text{ km s}^{-1})^{-3/2} \text{ Hz} \quad (9)$$

If the emission is proportional to the available flux of gravitational potential energy passing across each shell ($L \propto GM\dot{m}/r$, where \dot{m} is the accretion rate in gm s^{-1}) then the radio emission spectrum will vary as

$$L_\nu \propto \nu^{1/3}, \nu \leq \nu_p(2m) \quad (10)$$

in rough agreement with observations below 10^{11} Hz (ref. 1). For each of the BL Lac-type objects the radio emission is only a small fraction of the total luminosity. In the case of BL Lac, $L_{\text{radio}}/L_{\text{IR}} < 0.04$. Since the proposed synchrotron emission process itself converts only a small fraction of the available gravitational energy into radiation ($\sim 0.01\beta$), the conversion of gravitational energy into radiation by plasma oscillations can be quite inefficient and still produce the required flux.

Predictions

Model calculations⁷ predict that, in addition to infrared and optical radiation, a high energy tail of γ -ray radiation between 1 and 10 MeV will be emitted due to electron-proton and electron-electron bremsstrahlung in the plasma. The total bremsstrahlung luminosity is

$$L_B \simeq 2 \times 10^{26} (T_0/10,000 \text{ K})^{-3} (M/10M_\odot)^3 (n_0/10 \text{ cm}^{-3})^2 \text{ erg s}^{-1} \quad (11)$$

Unfortunately, for typical interstellar conditions and stellar-mass black holes, this γ -ray flux is far below the detectability limit of modern devices, even for nearby objects.

Rough estimates indicate that there may indeed be a finite number of stellar-mass black holes close to the Earth as required by the theory. From the known stellar birth rate function in the disk, stellar evolution time scales, and numerical computations of supernova explosions, it has been estimated⁹ that as much as 1% of the mass of the Galaxy may now be in the form of black holes with masses $\geq 10M_\odot$. This implies a local space density of black holes

$$n_{bh} \sim 2 \times 10^{-3} \text{ pc}^{-3}, \quad (12)$$

indicating that there could be eight such objects within 10 pc of the Earth.

A proper evaluation of the proposed model is not possible without a reliable determination of the distances to the objects. According to Pigg and Cohen²¹, the 21-cm absorption profile of BL Lac suggests that the object is at least 200 pc away and may be extragalactic. This lower limit would be substantially overestimated if a dense interstellar cloud is associated with BL Lac. If BL Lac and the other such objects are located within a few tens of parsecs of the Earth, their proper motions could be detected by both optical and radio techniques.

If it is determined that the BL Lac-type objects do indeed lie outside of the galactic disk, a black hole accretion model may still apply if any of the following are true:

(1) The infalling material possesses sufficient angular momentum to form an accretion disk about the black hole. In this case, the conversion of gravitational energy into infrared radiation *via* synchrotron emission may be far more efficient than in the case of spherical accretion, even for stellar-mass objects and typical interstellar conditions.^{6,22}

(2) The Lacertids are clusters or loose associations of stellar-mass black holes.

(3) The Lacertids are supermassive black holes situated in the galactic halo or at greater distances⁶.

These three possibilities clearly require further theoretical investigation.

Restoration of specific immunological virginity

I. McConnell, P. J. Lachmann & M. J. Hobart

Department of Immunology, Royal Postgraduate Medical School, Ducane Road, London W12, UK

The specific abrogation of an established immune response was studied by removing in vivo most of the immunocompetent lymphocytes reactive against the specific antigen, thus restoring the animal to a state of specific immunological virginity.

THE specific abrogation of the allergic response *in vivo* has been described in various experimental systems. In the induction of immunological tolerance^{1,2}, there is a central failure of the allergic response either as a result of clonal elimination or inactivation of specific antigen-sensitive cells. The existence of serum blocking factors which prevent the expression of an established allergic response has recently been described^{3,4}. In this case antigen-specific lymphocytes exist *in vivo* but fail to express their specific reactivity on account of serum blocking factors thought to be immune complexes⁵.

Here we describe another approach to the specific abrogation of an established immune response. This has been done by removing *in vivo* most of the immunocompetent lymphocytes reactive against a given antigen thereby restoring a primed animal to a state of specific immunological virginity.

Model system

The system makes use of a model^{6,7} involving cannulation of the efferent lymphatic from a single lymph node in sheep and subsequent drainage of lymph from the cannulated node. In this model it has been shown⁷ that macromolecules and lymphocytes which enter the parenchyma of a lymph node, leave the node only by way of the efferent lymphatic and cannot re-enter the peripheral blood directly from the lymph node.

We wondered whether there is an antigen-specific, selective mechanism in stimulated lymph nodes which enhances the entry into the node of lymphocytes specific for the antigen. If this is so, then by draining the efferent lymph from an antigen stimulated node, it should be possible to specifically abrogate the response of a primed animal, restoring it to a state of specific immunological virginity.

Random bred ewes from 1-4 yr old were injected with 2.5 human doses of BCG (Bacillus Calmette Guerin) and then primed to fluorodinitrobenzene (FDNB) by skin painting both ears with 100 μ l of FDNB in a 1:1 solution of acetone and olive oil. The animals were injected 10 d later with 10 mg of rabbit gamma globulin (RGG) and finally with 10 mg of NIP chicken globulin (NIP-CG). The injection schedule was phased to avoid antigenic competition⁸ and all injections were

Fig. 1 Kinetics of lymphocyte output in the efferent lymph of BCG sensitive sheep after repeated stimulation of the cannulated lymph node with PPD. Heavy arrows indicate injection of 100 μ g PPD in saline.

given intramuscularly in the shoulder region. The hapten NIP (4-hydroxyl-5-iodo-3-nitrophenacetyl-) was conjugated to CG as described⁹, the resulting molar ratio being 15 NIP groups per CG molecule. Both RGG and NIP-CG were given as alum precipitates together with 4×10^8 heat killed *B. pertussis*. The sheep were thus primed to two haptens and several protein carriers.

The popliteal lymph node was then cannulated and both lymph and lymphocytes collected twice a day for 3–4 weeks. During this time PPD (purified protein derivative of tuberculin, Batch 288, Central Veterinary Laboratories, Weybridge, Surrey) was injected repeatedly into the drainage area of the node. The second local challenge with PPD was given as NIP-PPD (mean conjugation ratio 0.5 NIP groups per PPD molecule) and the anti-NIP response measured in both efferent lymph and serum. This assays for PPD-specific 'helper' T cells.

Response

After 3–4 weeks cannulation was stopped and the systemic T cell reactivity of the whole animal to PPD and other antigens was measured both by skin testing and the 'helper' T cell assay using hapten-carrier conjugates. Antibody to the hapten (NIP) is formed only if there are helper T cells present which recognise the carrier, PPD or CG (ref. 10). The hapten-binding

Fig. 2 Challenge of cannulated lymph nodes with NIP-PPD. Anti-NIP response in blood and efferent lymph following local challenge of the cannulated lymph nodes with NIP-PPD. Antigen binding capacity (ABC) in serum or lymph expressed as units of antibody ml^{-1} of neat serum or lymph. ●, Lymph ABC; □, serum ABC.

capacity (ABC) of the serum or lymph was measured by the Farr Assay¹¹ using 10^{-8} M N^{125}I caproic acid as hapten¹². The antigen binding capacity was calculated from the linear portion of the binding curve between 3% binding (1 unit of antibody ml^{-1}) and 30% binding (10 units of antibody ml^{-1}). Sera or lymphs were serially diluted such that two dilutions lay between 3 and 30% binding.

The kinetics of lymphocyte output in the efferent lymph of two cannulated sheep are shown in Fig. 1. In each case local challenge of the node with PPD produced a typical response in lymphocyte output characterised by a period of cell shutdown lasting 20 h followed by a large increase which is nearly always biphasic. The magnitude of the response decreased with repeated challenge.

During this response the second injection of PPD was given as NIP-PPD and the anti-NIP responses measured in both efferent lymph and blood. The first two sheep (Fig. 2) showed a brisk response to the hapten in the efferent lymph of the stimulated node. There was, however, no concurrent antibody response in the serum of these sheep, indicating that neither antigen nor antibody reaches the general circulation from the stimulated node. Thus PPD-specific T cells are present in the cannulated sheep at this stage and cooperate with hapten-specific B cells to initiate antibody formation to NIP.

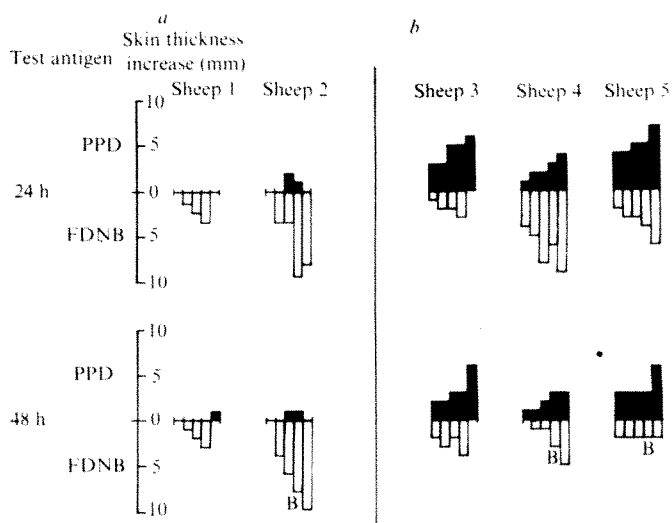

Fig. 3 Delayed hypersensitivity skin reactions to intradermal challenge with PPD and FDNB in cannulated (a) and control (b) sheep. PPD used at 6, 12, 25, 50 and 100 μ g. FDNB (100 μ l) used at concentrations 0.1, 0.2, 0.5, 1 and 2%; B, biopsy.

In the third sheep an anti-NIP response was detected in the serum as well as in the lymph. This cannulation stopped spontaneously after 8 d so it is likely that either collateral efferent lymphatics or lymphatic-venous connections had developed, affording systemic antigen escape and stimulation.

After five injections each of 100 μ g PPD into the drainage area of the popliteal lymph node, the cannulations were stopped and the sheep tested systemically for delayed hypersensitivity skin reactions to PPD and FDNB by intradermal challenge on the flank. In contrast to the control sheep (Fig. 3) the cannulated sheep were virtually skin-test negative at 24 and 48 h after intradermal challenge to concentrations of PPD ranging from 6 to 100 μ g. Two of the control sheep (3 and 4) were challenged five times at approximately 100 h intervals with 100 μ g of PPD into the drainage area of the right popliteal lymph node, before intradermal challenge. Other control sheep were not injected with PPD before intradermal challenge and produced in each case similar reactions to PPD (sheep 5).

To check the specificity of this unresponsiveness the same sheep were similarly skin tested with FDNB (Fig. 3). In each

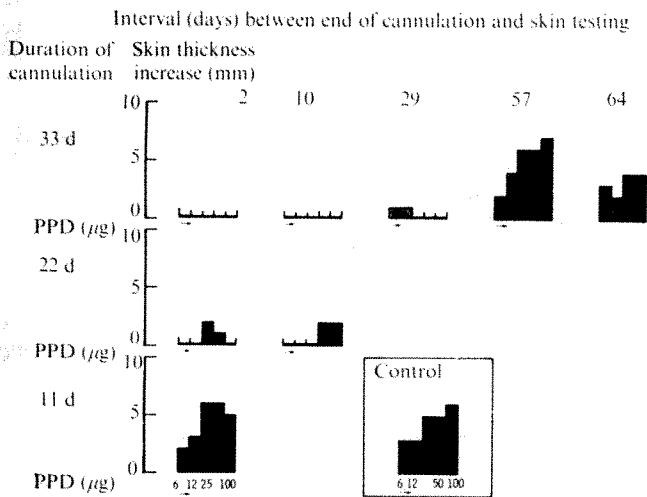

Fig. 4 Delayed hypersensitivity skin reactions to PPD in sheep cannulated for intervals of 33, 22 and 11 d and tested at several intervals after cannulation had stopped. PPD concentration as for Fig. 3.

case 100 μl of FDNB at concentrations ranging from 0.1–2% in 4:1, acetone:olive oil was painted on the left flank. As shown in Fig. 3, there was little difference between cannulated and control sheep with respect to their delayed reactions measured at 24, 48 and 62 h after challenge. In non-FDNB primed sheep (sheep 5), challenge with FDNB produced a marked inflammatory response with skin thickening which is largely due to oedema and infiltration of the site with polymorphonuclear leukocytes. This nonspecific reaction, can obscure the specific response particularly at 24 h, but by 48 and even 62 h later the inflammatory response decays whereas in primed sheep the delayed reaction persists. Skin biopsies of the reaction to 1% FDNB in primed sheep showed typical mononuclear infiltration and histologically both cannulated and control sheep were indistinguishable. Although the cannulated sheep were not skin tested with PPD before the start of cannulation it was noted that the first few injections of PPD below the lymph node produced a strong delayed reaction in the tissues surrounding the injection site.

The delayed hypersensitivity reactions to PPD of sheep cannulated for various days and then tested at frequent intervals after cannulation had stopped are shown in Fig. 4. It seems that sheep have to be cannulated for at least 21 d before they

Fig. 5 Serum antihapten response in cannulated and control sheep after intravenous challenge with NIP-PPD and then NIP-CG. Serum ABC are expressed as units of antibody ml^{-1} neat serum. ●, Cannulated; ▲, control.

become specifically unresponsive to the antigen used. A sheep cannulated for only 11 d and injected three times with PPD showed little diminution in its delayed reaction to PPD. The reappearance of PPD reactivity in the sheep cannulated for 33 d is presumably due to the fact that BCG vaccination is a living infection and antigen persisting within the macrophages of the cannulated sheep stimulates virgin T lymphocytes as they emerge from the thymus.

Delayed hypersensitivity skin reactions are only one measure of T cell function. Attempts were also made to determine whether this specific unresponsiveness was also reflected at the level of specific 'helper' T cells, by challenging the sheep

Fig. 6 Hypothetical models to explain specific depletion of antigen-reactive lymphocytes from the whole animal. *a*, Specific entry to lymph nodes; *b*, random entry with specific trapping. Explanation in text. PPD, PPD-reactive lymphocytes. CG, CG-reactive lymphocytes. LN, Lymph node. PCV, Post capillary venule. PPD/CG, ratio of specific cell types in lymph node.

with NIP-PPD at a time when they were still unresponsive to PPD. This has been done in two sheep with the same result, the typical response in one of them being shown in Fig. 5. Compared with the control, cannulated sheep fail to make any serum anti-NIP response on intravenous challenge with NIP-PPD. This unresponsiveness of 'helper' T cells was also found to be specific since challenge with NIP-CG 10 d later when the animals are still unresponsive to PPD (see Fig. 4) does result in an anti-NIP response, which was approximately 70% of that seen in control sheep.

Using these two criteria of specific T cell function, the results indicate that cannulation of the efferent lymphatic from a single lymph node of primed sheep, together with repeated stimulation of the cannulated node results in specific abrogation of the allergic response to the stimulating antigen. This

phenomenon is similar to that in which the lymphocytes involved in the mixed lymphocyte reaction can be specifically depleted from the total recirculating pool when allogeneic lymphocytes are injected into a cannulated lymph node (ref. 13 and R. S. Cahill, H. Frost, and Z. Trnka, in preparation).

Removal of antigen-reactive lymphocytes?

Our explanation for this phenomenon is that there is an antigen specific selective mechanism operating at the level of stimulated lymph nodes which specifically removes antigen-reactive lymphocytes from the total recirculating pool. Since T cells are predominantly a mobile population of cells the net result of this mechanism is to specifically deplete antigen-reactive T lymphocytes from the entire animal.

Other explanations based on some form of tolerance induction² or specific desensitisation¹⁴ would demand that either antigen or blocking factors entered the systemic circulation from the lymph node. Failure to produce a serum antibody response following local challenge of the node with NIP-PPD whilst sustaining an anti-NIP response in the efferent lymph is evidence that neither antigen nor antibody reaches the systemic circulation from the lymph node and exits only through the cannulated efferent lymphatic. In two similarly injected control animals the skin reactions to PPD in one were slightly weaker than noninjected controls but there was no difference in their anti-hapten response after challenge with NIP-PPD. This indicates a slight degree of desensitisation in such animals with regard to delayed hypersensitivity skin reactions, but this is not reflected at the level of 'helper' T lymphocytes.

At least two mechanisms can be proposed to explain antigen specific selection (Fig. 6). Assuming that the proportion of PPD-reactive and CG-reactive lymphocytes are the same in peripheral blood (PPD/CG=1) then if lymphocytes only crossed the high endothelial cells of the post-capillary venule (PCV) randomly this ratio would remain the same and systemic depletion, when it did occur, would be non-specific. To explain specific depletion it could be argued that over and above random entry into stimulated lymph nodes there is a specific entry mediated by antigen attached to the luminal surface of the high endothelial cells of the PCV which preferentially selects PPD-reactive lymphocytes into the node (Fig. 6a). The net result is that within the node the ratio of PPD-specific: CG-specific lymphocytes is greater than 1 and specific depletion from the peripheral blood gradually occurs. It seems likely that at each passage through the lymph node only a fraction of the specific cells would be removed at any one time.

There is a precedent for membrane-bound antigen attached to the surface of macrophages¹⁵ in lymph nodes but not as yet for endothelial cells. Since there is ample functional evidence to show that antigen never escapes systemically from a stimulated node^{7,16} such a model would demand that the antigen once bound to the surface of the high endothelial cell was rarely released into the circulation.

The alternative explanation is one which challenges the accepted fact that lymphocytes only move from blood to lymph and never in the reverse direction¹⁷. In this model (Fig. 6b) a proportion of the cells which enter the node then travel in the reverse direction from lymph node to blood. In stimulated nodes, antigen within the node specifically blocks the return of PPD reactive lymphocytes but not of CG-specific cells and again the net result in time, is a specific, systemic depletion of PPD reactive lymphocytes. The specific trapping of lymphocytes by antigen and their subsequent disappearance from the thoracic duct lymph has been described in other systems¹⁸⁻²⁰.

Our results at this stage do not enable a choice to be made regarding mechanisms but they do raise some interesting questions concerning the physiology of lymphocyte traffic (or circulation).

Finally, we point out that the experimental system described here affords a simple surgical means of specifically abrogating the allergic response of a primed animal to a given antigen. It remains to be seen whether this approach can be exploited in organ transplantation or in the specific abrogation of autoallergic disease.

We would like to thank Professor F. R. Bell and Dr A. Longstaffe of the Department of Veterinary Medicine, Royal Veterinary College, London for providing facilities and assistance in maintaining animals. We would also like to thank Denis Wilson, G. Kenny, J. Ranniwalla and D. Napier for technical assistance. This work was partly supported by the Cancer Research Campaign.

Some new concepts in immunological phylogeny

W. H. Hildemann

Department of Microbiology and Immunology and Dental Research Institute, University of California, Los Angeles, California 90024

Immunocompetence is first evident at the invertebrate level in coelenterates. Primordial cell-mediated immunity revealed by specific allograft reactions with at least short term memory is demonstrable in advanced invertebrates, whereas integrated cell-mediated and humoral immunity evolved progressively with the vertebrates.

SPECIFIC immunological competence with long lived memory is found in all vertebrate immune systems, associated with lymphoid cells, a thymus equivalent and the ability to produce serum antibodies. Two major pathways determining cellular (T lymphocyte) and humoral (B lymphocyte) immunity can be distinguished in all classes of vertebrates. Though most primitive among vertebrates, hagfish and lampreys (Cyclostomes) reject skin allografts

with concomitant development of specific immunological memory and produce IgM-type antibodies to potent xenogeneic antigens'. Given such impressive capacity at this level of phylogeny, one must look to the invertebrates for the origins and early mechanisms of immunocompetence. Until recently, little was known about the molecular defence mechanisms of invertebrates beyond nonspecific phagocytosis. We now know that rudimentary immune responsiveness with at least short term memory exists among certain advanced invertebrates. At still lower levels of phylogeny, immunorecognition and immunoincompatibility reactions with impressive specificity are demonstrable, but a memory component is doubtful². In spite of information gaps, a new conception of immunoevolution is emerging: essential cellular (T-cell) immunocompetence evolved progressively among metazoan invertebrates long before the additional (B-cell) vertebrate capacity to produce immunoglobulin antibodies.

The best studied and highest level of immunoevolution characteristic of all vertebrates can be designated 'integrated cell-mediated and humoral antibody immunity'. The cytoarchitecture of the lymphoid system and the molecular diversity of antibodies produced attain progressively higher levels of complexity in the evolution from fishes to mammals²⁻⁴. Circulating immunoglobulin antibodies of one or more molecular classes are inducible in vertebrates (B-cell pathways) in addition to immunorecognition and cell-mediated immunity reactions (T-cell pathways) also evident in invertebrates². Elaborate homeostatic regulation, including still poorly understood T and B-cell cooperation and suppression, is operative in birds and mammals. This can be regarded as the 'Rolls-Royce model' of immunoresponsiveness with numerous interdependent pathways (Fig. 1).

Important details of immunoregulation, especially tolerance, immunological blocking, memory and mechanisms of specific cell-mediated immunity, remain controversial or unknown. To pursue the Rolls-Royce analogy, a less elaborate Land Rover model of essential immunocompetence is found among fishes and amphibians, while bicycle models now appear characteristic of invertebrates. Depending on the environmental circumstances of course, the bicycle or Land Rover may be superior to the Rolls-Royce. One looks then for adaptive specialisation of the defence mechanisms among distinctive groups which have survival value or assure the integrity of the body. Among vertebrates, progressive diversification in molecular classes and subclasses of immunoglobulins is evident in the transitions from primitive fishes to mammals^{4,5}.

The ancestral immunoglobulin gene probably coded for a polypeptide of 110-112 amino acids corresponding to the

separate constant and variable region domains of antibody molecules⁶. By gene duplication and diversification of heavy and light polypeptide chains presumably guided by adaptive selection, the IgM immunoglobulin found in all vertebrates had already evolved in Cyclostomes several hundred million years ago. Why this complex antibody protein should be primitive is still puzzling, although its polymeric structure and multiple antigen-binding sites obviously increase the probability of combination with any antigen that has entered the body. Even at this level, further adaptive specialisation is apparent: IgM is tetrameric in bony fishes, hexameric in anuran amphibians and pentameric in certain sharks and mammals. Moreover, both lymphocyte and granulocyte-series of immunocytes are found in advanced invertebrates and all vertebrates, but the cytoarchitecture of the lymphoid system varies greatly at different levels of phylogeny⁷. Clearly different groups of animals have evolved different immunological equipment to meet their needs.

Primordial cell-mediated immunity

The capacity to develop specific transplantation immunity with concomitant immunological memory has been demonstrated in two phyla of advanced invertebrates—annelid worms^{8,9} and echinoderms^{2,10}. Echinoderms are more immediately ancestral to the vertebrates whereas annelids represent a line of evolution which diverged early from the progression leading to vertebrates. Slow but specific rejection of orthotopic integumentary allografts has been found in several species of earthworms, sea cucumbers and sea stars. The earthworm story is complicated by the unexplained intrapopulation compatibility *versus* incompatibility between geographically separate populations. However, integumentary xenografts between earthworm species are invariably rejected after a compatible healing-in period of considerable duration. At least short term immunological memory is evident in earthworms as revealed by accelerated rejection of repeat grafts placed at the time of or soon after initial rejection. However, the memory situation is more complex as indicated by prolonged survival of repeat grafts placed some time after initial allograft or xenograft rejection. Apparently, memory can be either short or long lived and positive or negative in its effect on foreign tissue survival in worms. This is an intriguing problem of specific immunoregulation. The observed transplantation immunity in worms is inherent in populations of leukocytes (coelomocytes) as shown by adoptive transfer experiments. Passive transfer of immune serum is without effect and immunoglobulins have not been detected in annelids.

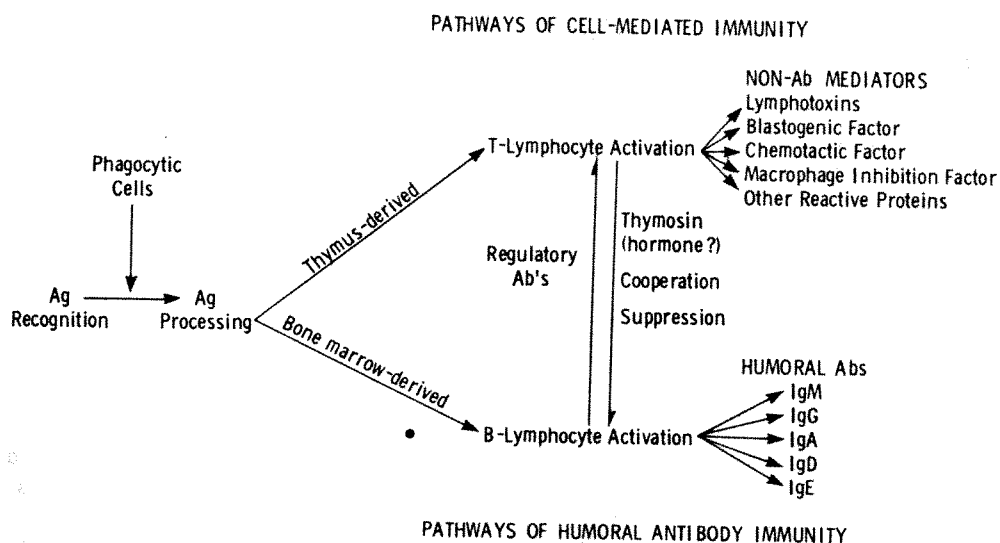

Fig. 1 Integrated pathways of cell-mediated and humoral antibody immunity at the mammalian level of immunoevolution. Elaborate and as yet poorly understood regulatory mechanisms are involved.

Echinoderms, even more than annelids, possess a rich assortment of leukocyte types, including distinctive lymphocytes, granulocytes and macrophages. Thus, mammal-oriented immunologists should not be surprised at the mounting evidence of immunological competence in the form of primordial cell-mediated immunity (PCMI) in these advanced invertebrates. Specific allograft immunity with at least short term memory was found in a sea cucumber (*Cucumaria tricolor*)¹⁰. Similar allogeneic incompatibility has now been found in two sea stars, *Protoreaster nodosus* from Australia¹⁰ and *Dermasterias imbricata* from California (Karp and Hildemann, unpublished). Leukocytes of multiple types, including macrophages, small lymphocytes (haemocytes) and eosinophilic granulocytes, were observed to infiltrate echinoderm allografts. Although the histological picture and chronic inflammatory reactions accompanying allograft rejection in these species are similar to those seen in vertebrates, the memory component may be distinctive. Experiments now in progress in our laboratory to compare the kinetics and consequences of short term compared with long term memory could be decisive in defining possible limitations of PCMI.

The lore of cell-mediated immunity (CMI) in mammals has expanded rapidly in recent years. The responsible cells are thought to be thymus-derived or T lymphocytes which originate in bone marrow. However, macrophages, granulocytes or equivalent cells cooperate critically with T lymphocytes, especially in the killing of foreign target cells. Moreover, T lymphocytes have a long life span and constitute the predominant small lymphocyte in the circulation as shown by their distinctive antigenic markers. Also T cells are the reservoir of long term immunological memory and are generally required as so-called helper T cells for the activation of antibody-producing B lymphocytes. Mammalian T cells are also distinguished by their characteristic responses to mitogens, such as phytohaemagglutinin (PHA), concanavalin A and *E. coli* lipopolysaccharide, reactivity in allogeneic mixed lymphocyte culture (MLC) reactions, and ability to mediate allograft reactions or delayed hypersensitivity reactions. The extent to which these properties of T cells persist as such throughout phylogeny remains to be determined.

Karp, Reddy, Tam and I (unpublished work) are variously investigating T cell type responsiveness in an echinoderm (*Dermasterias*), a tunicate (*Ciona*), a hagfish (*Eptatreus*) and a shark (*Heterodontis*) which together represent a transition group between the advanced invertebrates and lower vertebrates. Although all show similar patterns of chronic allograft rejection even at elevated water temperatures as evidence of PCMI, not even the hagfish and sharks seem capable of serum alloantibody responses. Blood leukocytes from these four species in culture respond distinctively to certain mitogens. Specific cell-surface recognition units or ancestral immunoglobulin receptors could be detectable on echinoderm or protochordate lymphocytes and pertinent results should be forthcoming. In short, although we are a long way from understanding cellular immune functions in phylogenetic perspective, the fact of cell-mediated immunity in advanced invertebrates is unassailable¹. Such CMI is sharply discriminating at the level of antigen recognition, but could be primordial in lacking diversification of effector functions or a long term memory component.

Immunorecognition and immunoincompatibility

Allogenic transplants in ciliate protozoans and free living amoebae remain viable, but intergenus or xenogeneic transplants have always resulted in eventual cell death¹. No immunological component is evident in the incompatible combinations. Interspecies incompatibilities in sponge cell aggregation seem to depend on binding affinities of cell-surface glycoproteins rather than any immunological

surveillance system¹¹. Species-specific adherence of sponge cells is analogous to tissue-specific cell aggregation in higher animals. No cell damage or killing has been reported as a result of incompatible sponge cell reactions, although this possibility deserves closer inspection. However, immunorecognition or capacity for non-self recognition of allogeneic tissue followed by incompatibility reactions seems characteristic of the Coelenterata or Cnidaria. Indeed, allogeneic incompatibility is now well documented in colonial hydroids¹², gorgonians¹³ and hard corals¹⁴. Straightforward enzyme-substrate or biochemical incompatibilities are not responsible, because allografts and even xenografts heal compatibly for days or weeks before tissue destruction occurs. I would now designate this 'immunorecognition/immunoincompatibility' because of the apparent specificity of the antagonistic reactions and the compatible lag period preceding manifestations of incompatibility.

The experimental evidence concerning allogeneic incompatibilities in coelenterates detailed in the references cited above can be summarised briefly. Allogeneic colonies of the hydroid *Hydractinia echinata* fail to fuse when grown in contact, whereas colonies derived asexually from single colonies merge compatibly. Hyperplastic growth occurs in areas of direct contact between two incompatible colonies and regression of the overgrown colony usually ensues. A hierarchy of hyperplastic potential was found among diverse strains of *Hydractinia* and breeding experiments revealed complex genetic control of histocompatibility¹². Both allografts and xenografts in gorgonian corals are subject to rejection, but control autografts survive indefinitely. Ectodermal as well as ectodermal-mesogial grafts are reported to behave similarly. Incompatibility reactions were scored as greater with xenografts (*Eunicella stricta* \rightleftharpoons *Lophogorgia sarmentosa*) than with allografts¹³. Surprisingly, disintegration of foreign transplants began after 4–5 d, even at the low temperature of 10°–15° C. Tests of specificity of rejection or immune memory have not been reported.

Staghorn corals of *Acropora* species are also amenable to decisive tissue transplantation experiments¹⁴. Branches from the same colony or clone fuse compatibly after 6–7 d in contact at 25° C and persist indefinitely with no sign of antagonism. Intercolony allografts generally show moderate incompatibility leading to soft tissue (coenenchyme) destruction in the contact zone, several to many weeks after initial functional fusion. Probable xenografts between *Acropora* species of uncertain taxonomic status yield detectable soft tissue death at the interface as early as a week after contact is made. Functional graft survival is easily tested by focal probing of polyp tentacles, which induces a withdrawal response instantly transmitted across a viable graft-recipient interface through the nerve net. Compatible coral grafts exhibit intact polyps and persistence of pigmented zooanthellae in the coenenchyme in zones of contact just as found in normal tissue. To what extent sharp immunological specificity or possible memory is involved in chronic rejection of allografts and subacute rejection of xenografts among these various coelenterates remains to be ascertained.

Tunicates of the protochordate group are generally held to be immediately ancestral to the vertebrates, thus being advanced invertebrates far removed from the coelenterates. As might be expected, tunicates have differentiated leukocytic cells including abundant lymphocytes. Immunoincompatibility or transplantation immunity at the level of colony specificity is common in colonial tunicates such as *Botryllus* species¹⁵, *Perophora viridis*¹⁶ and *Amaroecium* species¹⁷. The tunic and vascular stolon of compatible colonies placed in contact fuse to form a continuous tube with exchange of blood cells. With histoincompatible colonies the tunic at the site of contact thickens without fusion and local necrosis

may subsequently occur similar to the allogeneic reactions characteristic of coelenterates. Our tests for allogeneic immunoincompatibility in the solitary tunicate, *Ciona intestinalis*, show capacity to recognise and reject orthotopic allografts of integument in contrast to persistent survival of control autografts (Reddy, Bryan and Hildemann, unpublished). *Ciona* lymphocytes also respond to PHA in a manner similar to mammalian T lymphocytes. Tests with other mitogens and of MLC reactivity are underway. Existence of PCMI with memory as found in echinoderms remains to be shown in tunicates, but the precedent capacity for immunorecognition/immunoincompatibility is surely well developed. The latter capacity then may be predicted for all invertebrates amenable to testing.

MLC-type reactions in mammals, and, one would predict, other vertebrate classes, display essentially the same properties of inducible incompatibility that are found in coelenterates and tunicates. Positive reactions between allogeneic lymphocytes are reflected in new DNA synthesis and appearance of blast cells suggestive of the hyperplastic contact reactions seen in coelenterates. In mice, rats and humans, the capacity of lymphocytes to respond in MLC can be separated from the CMI capacity to kill foreign cells or reject allografts^{18,19}. Since the MLC reaction requires the two populations of cells to be alive and antigenically disparate, active immunorecognition is involved. Preimmunisation is unnecessary and a memory component is either not involved or has a short term effect on the degree of MLC responsiveness²⁰. The whole range of antigenic disparities from strong to weak can evoke positive MLC reactions¹⁹, although strong histocompatibility antigens yield the highest MLC responses in mammals²⁰. So MLC-type reactivity probably represents an ancient immunosurveillance mechanism which has persisted in phylogeny since the appearance of eumetazoan invertebrates. At lower levels of invertebrate phylogeny, immunorecognition precedes the occurrence of lymphoid cells as such, but the recognition function could be inherent in surface receptors of epithelial-type cells²¹. Allogeneic stimulation of the MLC-type is not a cytotoxic reaction. Subsequent generation of cells or molecules able to mediate the killing of foreign cells in close proximity, however, usually follows *in vivo*²².

Conflicting interpretations

All the evidence, taken together, suggests certain major sequential steps in the phylogeny of immunological reactivity (Fig. 2). The first level of cell-specific or species-specific aggregation is fundamental to all colonial or multicellular organisms. Epithelial or other cell surface proteins govern compatible tissue formation in plants, protozoans and sponges, but these, often exquisitely specific, reactions lack an immunological character in the strict sense that incompatible cell killing or heightened responsiveness are not inducible. Specific immunorecogni-

tion/immunoincompatibility is first evident at the invertebrate level of coelenterates, while cell-mediated immunity with at least short term memory has been detected initially in advanced invertebrates, notably annelids and echinoderms. There are obviously many information gaps in terms of invertebrate phyla not yet studied decisively or at all. I suggest that immunoincompatibility as regularly shown by allogeneic contact reactions is primitive and has persisted as an effective surveillance mechanism throughout metazoan phylogeny. MLC reactivity in modern birds and mammals is essentially similar to the allogeneic proliferative antagonism seen in coelenterates and tunicates. One may assume that progressively more differentiated leukocytic cells came to subserve this second level function as adaptive specialisation continued during phylogeny. Primordial cell-mediated immunity with memory constitutes a third level associated with cooperation of granulocytes and T lymphocytes in allograft rejection. This function becomes well developed in primitive fishes (cyclostomes and elasmobranchs) associated with longer-lived memory.

Integrated cell and humoral antibody immunity can be regarded as a fourth level development (Fig. 2) peculiar to vertebrates and perhaps restricted to advanced bony fishes and higher vertebrates. At this level helper T and B cells able to produce two or more molecular classes of antibodies are demonstrable. The cooperation of thymus-dependent lymphocytes (thymic hormone?) and certain B cells seems essential in mammals for the switch-over from specific IgM to IgG production²³. IgM production to quite potent immunogens may not require T and B-cell cooperation. Primitive fishes are capable only of IgM production to various antigens. Complex immunoregulation in birds and mammals (level 5) involves multiple molecular classes and subclasses of immunoglobulins in ways just beginning to be understood. The immunoregulatory mechanisms of primitive fishes making only IgM and of invertebrates with neither immunoglobulins nor a thymus gland are unknown.

Some immunologists are reluctant to accept the view that any adaptive immunity exists below the level of primitive fishes. Burnet²⁴ has considered that incompatibility in colonial tunicates and coelenterates as well as self-incompatibility in flowering plants are examples of self *versus* not-self recognition which are not analogous to the immunological processes of vertebrates. Similarly, Dausset *et al.*²⁵ regard the invertebrate incompatibilities as well as the MLC reaction in mammals as a non-immunological recognition system because a specific memory component is weak or absent. Other immunologists, however, view the allogeneic MLC reaction as an immunocompetent function and not simply the proliferative response of antigen-sensitive cells to contact with foreign cell membrane antigen^{20,22,26}. The point is that allogeneic stimulation may lead to the generation of cytotoxic lymphocytes with specific reactivity. The conflict

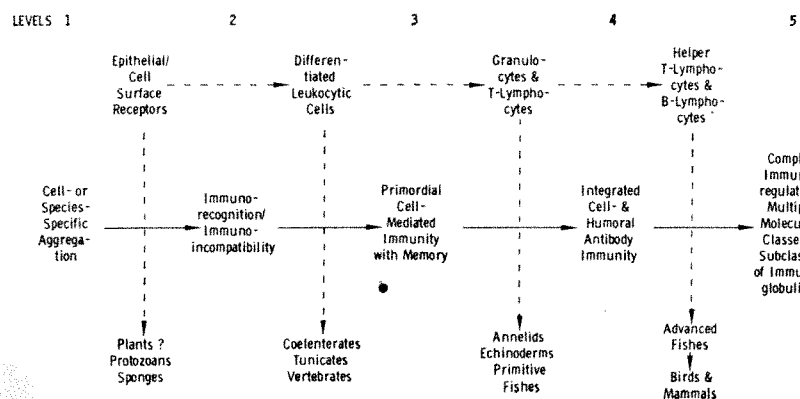

Fig. 2 Major steps in phylogeny of immunological reactivity. The suggested pathway is based on much new experimental evidence accumulated in recent years. Specific immunocompetence is already evident at the level of coelenterates, while cell-mediated immunity with memory is first detected in advanced invertebrates. Earlier manifestations of immunoreactivity seem to have been retained during progressive evolution and diversification of immunocyte functions.

is only partly one of definitions.

Extensive studies cited here indicate that immunorecognition/immunoincompatibility in coelenterates and tunicates involves not only non-self recognition of allogeneic tissue after initially compatible fusion; but also subsequent antagonistic reactions leading to localised cell death. In my view this constitutes the essence of specific, sharply discriminating, immune reactivity. Immunological memory associated with lymphoid cells may indeed be absent at the coelenterate level, but addition of these adaptive ingredients is clearly evident in echinoderms and probably also in tunicates. Available evidence suggests that cell-mediated immunity (T-cell function) evolved in invertebrates long before the additional vertebrate capacity for humoral antibody production (B-cell function). Among the vertebrates, progressive diversification of immunocyte functions appears correlated with increasing interdependence of the T and B-cell pathways. The supposition that immunological capacity paralleled leukocyte differentiation and evolved from no memory to short term to finally long term memory is attractive but unproved. Although the long known recognition system of nonspecific phagocytosis associated with the pioneering studies of Metchnikoff²⁷ is ubiquitous in metazoan phylogeny, granulocytes and other types of macrophages now appear to be critical participants in specific immune pathways and especially in cell-mediated immunity.

In essence, five levels of recognition and reaction to foreignness (Fig. 2) are now discernible in phylogenetic progression. All effective in maintaining the integrity of the organism and the species. If one demands both specificity and memory as qualifications for true immunological reactivity, then immunocompetence first appeared among the advanced invertebrates. But if the specific memory requirement is viewed flexibly also as an evolving characteristic, then immunocompetence is already manifest at the lower invertebrate level of coelenterates.

I thank L. Reddy, M. Tam and R. Karp for stimulating discussions. This work was supported by grants from the National Institutes of Health.

Three-dimensional structure of adenyl kinase

G. E. Schulz, M. Elzinga*, F. Marx & R. H. Schirmer

Max-Planck-Institut für Medizinische Forschung, Heidelberg, West Germany

A combination of X-ray data at 3 Å resolution and sequence results has yielded the atomic structure of adenyl kinase, a ubiquitous enzyme which catalyses the phosphorylation of AMP by ATP. The abundant secondary structures of the protein and the probable binding sites for ATP and AMP are described.

ADENYL kinase (adenylate kinase, EC 2.7.4.3) catalyses the reaction¹ $ATP + AMP \xrightarrow{Mg^{2+}} 2 ADP$. This interconversion of the adenine nucleotides seems to be of particular importance in organelles which have a high turnover of chemical energy, for example in chloroplasts², mitochondria³, or myofibrils⁴. With a molecular weight of 22,000 muscle adenyl kinase (myokinase) is the smallest of the known phosphoryl transferases⁵. Other kinases presently studied by X-ray

analysis have molecular weights of 40,000-100,000⁶⁻¹⁰.

A low resolution model of porcine muscle adenyl kinase¹¹ and its amino acid sequence¹² have been described recently. The X-ray analysis has now been pursued to higher resolution. A combination of 3 Å X-ray data and the sequence information yielded the atomic structure of the enzyme.

X-ray diffraction

It has been shown¹³ that porcine muscle adenyl kinase crystallises in one of the enantiomorphic space groups $P3_121$ or $P3_221$ with one molecule in the asymmetric unit. To find the correct alternative we made a separate measurement of 81 independent noncentric Friedel pairs with spacings above 10 Å (limit for negative Bragg angles on Siemens diffractometer) from the highly isomorphous CH_3HgNO_3 derivative. The observed structure factor amplitude difference within each Friedel pair was compared with the corresponding difference as calculated¹⁴ from the known protein structure factor¹¹ in conjunction with the known heavy atom structure factor¹¹. Correlation coefficients¹⁵ between observed and calculated differences were determined for both possible

* Present address: Boston Biomedical Research Institute, 20 Staniford Street, Boston, Mass. 02114.

space groups. They turned out to be +0.80 and -0.80 for space groups P3₂21 and P3₁21, respectively, indicating that the true space group is P3₂21. By chance, this space group had been selected when building the low resolution balsa wood model described earlier¹¹. Therefore, this model has the correct chirality.

The present structure analysis includes the 4,200 independent reflections that have spacings above 3 Å. For phase determination corresponding data sets were measured from the four heavy atom derivatives listed in Table 1. Reflection intensities were determined on an automated diffractometer following a procedure that has been described earlier¹¹.

Data were collected in shells of about 600 reflections each, that is, a complete data set contained seven shells. A separate measurement of about 500 reflections distributed over all shells was made for the protein and for every derivative. It overlapped with each shell in about 70 reflections. We used these overlaps to put the seven shells of a data set on a common scale. All data sets were then put on an absolute scale as derived from a Wilson plot¹⁸. This scale turned out to be 12% lower than the corresponding scale determined at low resolution¹¹.

All derivative data shells were corrected for systematic errors in the measurement before scaling and merging them to data sets. This correction was based on the assumption that the differences between derivative and protein structure factor amplitudes should be evenly distributed within a given shell. We checked for systematic deviations along the longitudinal and along the latitudinal coordinates on the surface of the shell. Such deviations were reduced by applying a correction factor to the derivative structure factor amplitude that was linear in both of these coordinates. The average correction on each amplitude was about ±2%. This is not negligible because the phase analysis is based on the rather small differences between derivative and protein structure factor amplitudes¹⁹.

In the refinement of heavy atom parameters and in the Fourier synthesis we omitted those reflections that have intensities less than twice the estimated error of the measurement. This reduced the amount of data by 8%. In the refinement we followed a procedure given by Dickerson *et al.*¹⁷. It alternates between evaluation of the best phases and parameter shifts. The refined parameters are listed in Table 1.

The accuracy of the analysis as a function of resolution is illustrated in Fig. 1. Most of the phase information is derived from the CH₃HgNO₃ and the K₂Pt(SCN)₆ derivatives because their heavy atom structure factors are much

higher than their lack of closure errors. The K₂Pt(NO₂)₄ derivative has a lower radial fall-off factor than the protein (see Table 1) and it is less radiation sensitive. Its contribution to the phase information, however, is rather poor. The lack of closure error exceeds the heavy atom structure factor at higher resolution. A second CH₃HgNO₃ derivative could be prepared by blocking the thiol groups asymmetrically with 6-thioinosine 5'-*o*-monophosphate (6-SH AMP) prior to soaking with CH₃HgNO₃, so that effective substitution numbers changed (Table 1). As judged from Fig. 1 a considerable amount of phase information is obtained from this derivative. One has to bear in mind, however, that this derivative is not very different from the other mercury derivative. Therefore, their contributions to the phase information are to some extent coupled. As shown in Fig. 1 the figure of merit for phases drops 96% at low resolution to 77% at high resolution, the average being 82%. These values indicate that the electron density map is of reasonable quality.

Electron density map

The 'best' electron density distribution¹⁹ was calculated using the phased structure factors weighted with the corresponding figures of merit. The electron density map was computed in sections 0.94 Å (=c/150) apart perpendicular to the c-axis. These sections were plotted on microfilm and subsequently redrawn on perspex sheets at a scale 1 Å=4 mm. The resulting small map was very useful for chain tracing as well as for assigning side chains and preliminary Cα-positions.

With the amino acid sequence of the protein¹² at hand, chain tracing was not a great problem. All 22 markers: 14 aromatic side chains, six methionine and two cysteine residues could be found in the map and fitted. There is no density that has not been accounted for. Other chain tracings which become possible if one concedes large errors in electron density invariably lead to contradictions. Therefore, the fit of the amino acid sequence into the electron density map seems to be unambiguous.

A comparison of the resulting molecular boundaries with those determined at low resolution¹¹ showed no difference except that about five residues at the N-terminus had been incorrectly assigned to a neighbouring molecule, that is, they are at a wrong place (around residue 50, see Fig. 2) in the low resolution balsa wood model¹¹.

* Centric reliability factor¹⁶.

† Scaling parameters: Initially all data sets were scaled to equal ΣF at low resolution. In the refinement a scale factor 1/K exp βS² with S=sin θ/λ was allowed for each derivative data set.

‡ Heavy atom positions in fractional coordinates.

§ Effective substitution number. Units are in numbers of electrons based on an absolute scale.

|| Radial fall-off factor¹⁷. The heavy atom structure factor is defined as $f_H = \sum_m Z_m \exp(-B_m S^2) \exp 2\pi i(hx_m + ky_m + lz_m)$ with the sum taken over all sites *m* of a derivative. The radial fall-off factor for the protein structure factor amplitudes is 9 Å².

The main sites of the K₂Pt(SCN)₆ and the K₂Pt(NO₂)₄ derivatives as well as the third site of the CH₃HgNO₃ and the only site of a HAuCl₄ derivative¹¹ are located at the His-36 side chain in the cleft region. The first and second CH₃HgNO₃ sites are at Cys-25 and Cys-187, respectively.

Fig. 1 Variation of root mean square (r.m.s.) heavy atom structure factors, r.m.s. lack of closure errors, and the figure of merit of the phases with resolution. Curves A, B, C, D are the r.m.s. heavy atom structure factors and curves a, b, c, d are the corresponding r.m.s. lack of closure errors for the derivatives: CH_3HgNO_3 , $\text{K}_2\text{Pt}(\text{SCN})_6$, $\text{K}_2\text{Pt}(\text{NO}_3)_4$, and $[\text{6-SH AMP} + \text{CH}_3\text{HgNO}_3]$, respectively. The plot is logarithmic with the resolution taken as $S^2 = (2 \sin \theta / \lambda)^2$. All r.m.s. lack of closure error curves have a trough at 5 Å corresponding to a similar minimum of the mean protein structure factor in this region. The overall mean figure of merit is 82%.

Description of the molecule

A stereo drawing of the polypeptide chain is given in Fig. 2. As with the low resolution balsa wood model¹¹ we selected the view that exposes the deep cleft. This cleft divides the molecule into two domains: The domain on the right side consists of three helical rods which enclose a

small hydrophobic core. The domain on the left side of Fig. 2 contains a parallel pleated sheet formed by five strands, each about five residues long. It has a right-handed twist like the pleated sheets in many other proteins²⁰. The sheet is the architectural centre of this domain. There are two hydrophobic cores, one on each side of the sheet. They are formed between the sheet and covering helices. About 55% of all residues are in right-handed helical configuration and 13% are in the sheet. Thus, about two thirds of all residues are involved in secondary structures. This probably accounts for the exceptional acid stability of adenylyl kinase⁴. Several parts of the helices seem to be distorted from the α -helical configuration²¹. The relation between primary, secondary and tertiary structure is illustrated in Fig. 3.

All charged side chains are on the surface of the molecule. Being situated deep in the cleft aspartate-93 is an exception. There is an unusual piece of chain containing five glycines and one proline between residues 15 and 22 (Fig. 3). As shown in Fig. 2 it is situated in the cleft forming a crooked loop as expected from such a sequence²³. This loop envelopes a dense narrow spherical peak that has double the height of the average backbone density. It is also higher and narrower than would be expected from a rigidly bound sulphate ion. Based upon height and width of the peak it seems to be due to a metal ion with an atomic number approximating those of Mn, Fe, Co, Ni, Cu, or Zn. Atomic absorption measurements on freshly prepared active adenylyl kinase, however, revealed none of these metals (Gastner, personal communication). We suspect that the enzyme has picked up a metal ion during the preparation of the crystals; possibly this metal ion indicates the location of the Mg^{2+} or Mn^{2+} during catalysis^{24,25}.

Location of active centre

Adenylyl kinase binds both AMP and ATP at specific sites¹. All attempts to bind substrates or substrate analogues to the crystals failed¹¹, and we must at this time rely upon indirect evidence to locate the active centre.

NMR data show that one of the two histidines in porcine muscle adenylyl kinase is involved in catalysis²⁶. His-36 is located in the cleft region and binds many heavy atom compounds (see Table 1) whereas His-189 lies flat on a very smooth surface of the molecule. Carp muscle adenylyl kinase contains only one histidine residue, and this is equivalent to His-36 in the porcine enzyme (von Zubern and Noda, personal communication). Since it is very likely that a residue involved in catalysis is conserved during species evolution²² we may assume that His-36 is at the active site, that is, that the active site is in the cleft region.

Fig. 2 Stereo drawing of polypeptide chain of adenylyl kinase. C α -atom positions are marked with circles. N and C termini as well as some residue numbers are inserted. In the electron density map the chain fades out between residues 137 and 141 in an exposed region on the surface of the molecule. This stretch of chain, however, is strongly connected in the 6 Å map and in an intermediate 4 Å map.

Fig. 3 Sequence of adenyl kinase in one letter notation²². Residues involved in helical structures and in the pleated sheet are drawn with heavier circles. The diagram indicates roughly the chain fold. The orientation of the molecule corresponds to that shown in Fig. 2. Helix 23-30 is above the plane of the paper and helices 100-107 and 144-164 are below.

The region around His-36 is rather conspicuous. Cys-25 is about 5 Å away. Such a close His-Cys-pair is probably also present in the active centres of creatine kinase²⁷ and of the Na-K-transport ATPase²⁸. Asp-93 is almost buried in the cleft. It may be hydrogen-bonded to His-36 and/or Cys-25. His-36, Asp-93, and Cys-25 are also present in the carp enzyme (von Zabern and Noda, personal communication). Ser-38 is very close to His-36 and Asp-93. The spatial relationship between these three residues, however, is that of an equilateral triangle and not that of a straight line as in the charge relay system of the proteases²⁹. The distances between the centre of the postulated metal ion and the centres of the side chains of His-36 and Asp-93 are 10 Å and 5 Å, respectively. There is sufficient space between His-36 and the postulated metal ion to accommodate a phosphoryl group. This group would also touch Asp-93. Moreover, there are several basic side chains in the cleft region. They might serve to neutralise the negative charges on the substrates.

There are two hydrophobic pockets nearby. One is formed in the region between Gly-20 and Val-179 (see Fig. 2), the other one between Gly-94 and Tyr-153, that is, in the cleft region. It seems geometrically possible to fill the first pocket with the adenine moiety of AMP and the second one with that of ATP in such a way that the phosphate group of AMP and the γ-phosphoryl group of ATP meet each other between His-36 and the postulated metal ion, that is, at Asp-93. This localisation of the substrates is comparable with the topology of the nucleotide binding sites in other proteins³⁰.

In the crystal the second pocket is partly covered by a neighbouring molecule. This might be one of the reasons why we have not succeeded in binding substrate to the crystalline enzyme so far. In future substrate binding studies we intend to concentrate on crystal forms of adenyl kinase¹¹ which have not yet been analysed.

We are indebted to K. Biedermann, G. Müller, and W. Sachsenheimer who contributed to this work; we thank Professor K. C. Holmes for encouragement and support.

Large flare on the red dwarf star UV Ceti

ATTEMPTS to measure radio emission occurring simultaneously with the sporadic optical flares on the red dwarf dMe type stars have been hindered by the rarity of large flares. Apart from one case of a flare with an unusually long duration and a peak magnitude of 1.7 (ref. 1) the correlation so far established has been limited to flares of about 1 mag or less^{2,3}. On October 11, 1972 we were able to obtain simultaneous radio and optical recordings of an unusually large flare on the star UV Ceti (L726-8AB) during which the apparent magnitude of the star increased by more than 4.55 mag.

The event occurred during the period of cooperative observations of this star⁴ (October 1–15, 1972). The observations described here were made simultaneously by the Mk 1A radio telescope at Jodrell Bank, and the 30-inch Cassegrain reflector (f/13.5) at the Stephanion Astronomical Station in Peloponnese. The radio telescope was working on a frequency of 408 MHz (± 2 MHz, ± 3 dB). The aerial received linear polarisation and the output was obtained by the digital sampling process¹. A radio source of known strength was used for calibration. A Johnson dual channel photoelectric photometer⁵ was used on the 30-inch reflector.

The raw data in the optical case consisted of the photoelectric intensity I_t (minus the sky background) during the flare, compared with I_0 , the photoelectric intensity (minus the sky background) for the quiet star. The light variation is plotted in Fig 1 as the variation in the b colour magnitude $\Delta m(b) = 2.5 \lg I_t/I_0$. During the peak of the flare between 21 h 18 min 5.2 s and 21 h 18 min 53.4 s UT the recording pen was off scale. The other interruptions in this record are caused by measurements of the sky background or by checks of the position of the star in the field of view of the telescope. In the radio case the data are the digital printout (logger units) from the sampling made five times a second and printed at intervals of 30 s. The scale of flux units at 408 MHz is derived directly from the similar digital printout on the calibration source (3C33). The calibration was made between 20 h 27 min and 20 h 43 min UT.

Fig. 1 The radio (A, 408 MHz) and photoelectric (B, b colour) records of the flare on UV Ceti on October 11, 1972. The ordinates for the radio record are digital logger units with 100 units = 5.3 flux units (10^{-26} W m⁻² Hz⁻¹).

No corrections have been made to these 408-MHz data plotted in Fig. 1 but because the flare occurred when the star was at an elevation of about 9° from Jodrell Bank there is a slight baseline slope caused either by ground effects or temperature drifts in the parametric amplifiers. The inclined abscissa indicates the estimated true baseline derived from recordings over the same azimuth-elevation range on preceding and following nights, when no flare occurred. In the case of the photoelectric records, measurements of a standard light source at 20 h 55 min and 23 h 06 min, differed by only 0.004 mag. Therefore, no corrections have been applied, and there are no corrections to $\Delta m(b)$ for atmospheric extinction. (The relative air-mass factors—secant of zenith distance—varied from 2.078 at 20 h 56 min, 1.777 at 22 h 44 min—upper culmination—to 1.787 at 23 h 06 min UT.) Measurements in the b colour of the companion star d (Fig. 1 of ref. 6) were made according to the recommendation of IAU Commission 27 (ref. 7). These measurements, at 20 h 56 min and 23 h 05 min UT were compared with the b colour measurements of UV Ceti at 21 h 06 min (quiescent state) and at 22 h 27 min UT. Flare star minus d were +0.54 mag and +0.45 mag respectively. The second order extinction coefficient K''_{b-v} at Stephanion is usually within 0.00 mag and -0.08 mag (ref. 8), and because $\Delta(b-v) \approx 1$ mag, the calculated values of these differences outside the Earth's atmosphere are approximately 0.62 mag and 0.52 mag respectively.

The rates of energy production during the flare are approximately 3.2×10^{25} erg s⁻¹ over a bandwidth of 400 MHz in the radio spectrum, and 2.5×10^{30} erg s⁻¹ over a bandwidth of 6.7×10^8 MHz in the optical spectrum. This ratio of 10^5 is similar to that for large solar flares but, as found in the previous measurements, the total energy output in the flare of 10^{31} to 10^{32} erg during the peak phase is at least equal to that of the normal photospheric continuum. In contrast, the total energy output of a large solar flare is equivalent to only about a millionth of the normal quiescent emission.

In many earlier radio-optical correlations there has been evidence that the peak of the radio emission follows the maximum phase of the optical flare by several minutes^{1,2}. The main feature of the correlation described here is the decisive evidence that the sharp front of the optical flare precedes that of the radio flare by approximately 8 min (the maxima are separated by 11 ± 1 min). The interpretation in terms of a solar flare type event in the atmosphere of UV Ceti is given in an accompanying paper⁹.

Model for a flare on the star UV Ceti

ON October 11, 1972 a large flare occurred on the star UV Ceti. It was observed simultaneously at photoelectric frequencies and at the radio frequency of 408 MHz (ref. 1). These observations provide enough information to describe a reasonably good model of the outer layers of the star, and of the overall mechanics of the flare.

The radio flare must have occurred in a region with low gas density, otherwise the radiation could not have propagated away. According to the observations there was a delay of about 500 s between the onset of the flare at optical and at radio frequencies. During this interval the disturbance from the optical flare must have spread through the corona of the star. The inevitable conclusion is that UV Ceti has a corona and a stellar wind. The energy required to heat the corona and to drive the wind must, presumably, come from the mechanical energy of the convective motions in and near the photospheric layers.

The general properties of flare stars have been described². For the star UV Ceti the data are as follows: mass = 10^{32} g, radius = 4.5×10^9 cm, and therefore surface gravity $g = 3.3 \times 10^5$ cm s⁻². When conditions are quiescent the surface temperature is $T_* = 3,000$ K, and the flux of radiation is 4×10^9 erg cm⁻² s⁻¹. The star has a surface area of 2.5×10^{20} cm² and its luminosity is 1.0×10^{30} erg s⁻¹.

Opacity tables³ can be used to construct a rough model for the atmosphere of the star. The table for an "Iben Mixture XII", with $X=0.8$ and $Z=0.01$, seems most appropriate. It becomes immediately apparent that the atmosphere must be convective even considerably above the level at which optical depth $\tau = 2/3$ is reached. The outer layers of the star are therefore fully convective; the pressure P is found to be 3.6×10^7 dyne cm⁻² and the density is 1.7×10^{-4} g cm⁻³ at $\tau=2/3$. The table given by Cox and Stewart³ has to be extrapolated to reach these values of pressure and density; the formula $\kappa = 9 \times 10^{-39} \rho^{0.45} T^{11}$ fits the opacity data reasonably well in the region concerned.

To generate a radiant energy flux of 4×10^9 erg cm⁻² s⁻¹ requires that the photospheric layer which can effectively radiate should have a surface density of 16 g cm⁻². As $\rho = 1.7 \times 10^{-4}$ g cm⁻³ this layer is only $\approx 10^5$ cm thick. Outside this layer the gas can hardly radiate at all.

The scale height, H , in the photosphere is about 6.5×10^5 cm and I assume that the mixing length for the convective motion is the same. To produce a convective flux of 4×10^9 erg cm⁻² s⁻¹ the rising and falling currents need an average speed $U = 2.0 \times 10^4$ cm s⁻¹, and a rising (or falling) element must have a temperature excess (or defect) of $\Delta T = 7$ K with respect to the mean temperature.

It seems probable that the convective motions will twist up any magnetic lines of force above the star. The turbulent pressure in the photosphere is $\rho U^2 = 6.8 \times 10^4$ dyne cm⁻². If this is equated to the magnetic pressure $H^2/4\pi$, then an estimate $H = 900$ gauss is obtained for the likely magnetic field strength at the surface of the star.

The photoelectric magnitude of UV Ceti increased by more than $\Delta m = 4.5$ during the flare¹. The peak increase lasted about 10 s. At 4,500 Å (a frequency of 6.7×10^{14} Hz) the normal energy output of the star is

$$\pi R^2 (8\pi h \nu^3 / c^2) \exp(-h\nu/kT) = 1.6 \times 10^{14} \text{ erg Hz}^{-1} \text{ s}^{-1}$$

An increase of 4.5 mag raises the energy flux by a factor of 63, to about 1.0×10^{16} erg Hz⁻¹ s⁻¹. Over a bandwidth of, for instance, 6.7×10^{14} Hz this corresponds to an energy output of 6.7×10^{30} erg s⁻¹ during the flare. But the optical flare is presumably a localised phenomenon above the surface of the star, not equally visible from all sides. I shall assume that the flare of October 11 was on the side facing the Earth. The energy received from it at the Earth would then be above average. I allow a factor 2.5 or 3 to take account of this. The estimate for the rate of energy production by the flare then becomes 2.5×10^{30} erg s⁻¹. Over a period of 10 s the energy output is 2.5×10^{31} erg.

The flare must occur in the lower corona. I shall take the ambient gas density there to be ρ_0 and the magnetic field strength in the region of the flare at the time of its occurrence to be H_0 . In accordance with the usual interpretation of solar phenomena I shall assume that the energy of the flare is released during the reconnection of the lines of force in a magnetic field. The Alfvén speed in the region will be $V_A = H_0 / (4\pi\rho_0)^{1/2}$; if L is the typical linear dimension of the flare region, the duration of the optical flare at its maximum can be estimated to be

$$\tau_0 = L/V_A = L\sqrt{4\pi\rho_0}/H_0 = 10 \text{ s} \quad (1)$$

The total magnetic energy in the flare region is

$$\mathcal{E}_0 \approx H_0^2 L^3 / 8\pi \quad (2)$$

If the light produced by the flare is a result of synchrotron radiation by fast electrons, then for the critical frequency $\omega_0/2\pi$ to be about right requires that, at the time of the optical flare,

$$\omega_{c,0} \approx 4.2 \times 10^{15} \approx \gamma_0^2 e H / mc \quad (3)$$

where $\gamma_0 mc^2$ is the typical energy of the electrons. If there are \mathcal{N}_0 electrons altogether, their total energy is $\mathcal{N}_0 \gamma_0 mc^2$ and their rate of production of radiant energy is

$$Q_0 = \mathcal{N}_0 \gamma_0^2 e^4 H_0^2 / m^2 c^3 = \mathcal{N}_0 \omega_{c,0} (e^3 / mc^2) H_0 \quad (4)$$

The estimate for Q_0 is 2.5×10^{30} erg s⁻¹. It follows from equations (3) and (4) that

$$\mathcal{N}_0 H_0 = 6 \times 10^{36} \text{ gauss} \quad (5)$$

But from relation (3) $\gamma_0 = 1.6 \times 10^4 H_0^{-1/2}$ and so

$$\mathcal{N}_0 \gamma_0 mc^2 = 10^{35} H_0^{-3/2} \quad (6)$$

is the total energy of the relativistic electrons present at any one time during the optical flare.

Further information can be deduced from the events following the visual flare. I postulate that after the reconnection of the lines of force a bubble of plasma with a magnetic field expands into the stellar corona, preceded by a shock wave. About 500 s later the bubble reaches the level at which radiation at 408 MHz can just propagate through the corona. I shall take this level to be at a height h_1 above the base of the corona. The local density of the plasma can be found from the condition that its refractive index is 0 at 408 MHz and this leads to $\rho_1 = 5 \times 10^{-15}$ g cm⁻³.

The expansion of the bubble can be described if something is known about the variation of density with height in the stellar wind. I assume the wind to be isothermal, with a pressure-density relationship $P/\rho = a^2 = \text{constant}$. Rough estimates indicate that the sonic point in the stellar wind will lie one or two stellar radii above the photosphere. In such a wind the variation of speed, u , with height is given by

$$(u - a^2/u) du = (2a^2/r - GM/r^2) dr \quad (7)$$

(see for example Kahn⁴). At the sonic point

$$u = a \text{ and } r = r_s = GM/2a^2 \quad (8)$$

To find how u varies with r near the sonic point put $u = a(1 + \epsilon)$ and $r = r_s(1 + \eta)$. With these substitutions equation (7) may be solved, correct to the second order in ϵ and η , in the form

$$\epsilon = \pm \eta \text{ or } u - a = \pm (a/r_s) (r - r_s) \quad (9)$$

The upper sign here applies for the case of a stellar wind, and the solution then simplifies to

$$u = ar/r_s \quad (10)$$

I shall apply this approximation all the way from the base of the corona to the level at which the 408 MHz radiation

can propagate. Then conservation of mass in the wind gives

$$\text{constant} = \rho v r^2 = \rho a^3 / r_s \quad (11)$$

and the density at height h above the photosphere is

$$\rho = \rho_0 R^3 / (R+h)^3 \quad (12)$$

Magnetic energy \mathcal{E}_0 is released in the lower corona during the visual flare. After time t the bubble has grown to linear dimensions h from its initial linear size L . Conservation of magnetic flux demands that the field strength should vary as h^{-2} , so that at the later time the energy content is $\mathcal{E} = \mathcal{E}_0 L/h$, the energy density is $\mathcal{E}_0 L/h^4$ and the magnetic pressure $P = \mathcal{E}_0 L/3h^4$. To expand, the bubble must push back the ambient coronal gas. The condition of momentum balance at the boundary of the bubble means that

$$P = \rho V^2 = \rho \dot{h}^2 \quad (13)$$

where $V = \dot{h}$ is the speed of expansion. It follows from equations (12) and (13) that

$$\rho_0 h^2 / (1+h/R)^3 = \mathcal{E}_0 L / 3h^4$$

and so the time τ_d required to reach height h_1 is given by

$$(\mathcal{E}_0 L / 3\rho_0)^{1/2} \tau_d = \int_0^{h_1} h^2 (1+h/R)^{-3/2} dh \quad (14)$$

The major contribution to the integral in this equation comes from the upper end of the range of integration, so that

$$\int_0^{h_1} h^2 (1+h/R)^{-3/2} dh \approx (2/3) h_1^{3/2} R^{3/2} \quad (15)$$

From equations (1) and (2) it follows that

$$(\mathcal{E}_0 / 3\rho_0)^{1/2} L^{1/2} = 6^{-1/2} (H_0^2 / 4\pi\rho_0)^{1/2} L^2 = 6^{-1/2} V_A L^2 \quad (16)$$

and so

$$6^{-1/2} L^3 \tau_d / \tau_0 = (2/3) h_1^{3/2} R^{3/2}$$

or

$$h_1 / R = (L^2 / R^2) (\tau_d \sqrt{3} / 2\tau_0 \sqrt{2})^{2/3} \quad (17)$$

For the flare of October 11, $\tau_d / \tau_0 = 50$, and the relationship becomes

$$h_1 / R = 9.8 L^2 / R^2 \quad (18)$$

Equations (1), (2), (12) and (18) together lead to a relationship between the energy \mathcal{E}_0 and linear dimensions L of the flare, in the form

$$\begin{aligned} \mathcal{E}_0 &= (1/2) \rho_0 V_A^2 L^3 = \rho_0 L^5 / 2\tau_0^2 = (\rho_1 L^5 / 2\tau_0^2) [1 + (h_1/R)]^3 \\ &= (\rho_1 L^5 / 2\tau_0^2) [1 + (9.8 L^2 / R^2)]^3 \end{aligned} \quad (19)$$

Inserting values for $\rho_1 \tau_0$ and R leads to the estimate in Table 1.

Table 1 Typical values for the parameters

L	10^9	2×10^9	3×10^9	cm
\mathcal{E}_0	8.3×10^{28}	2.2×10^{31}	1.0×10^{33}	erg
H_0	45	270	1,000	gauss

The results (Table 1) can be approximately represented by the formulae

$$H_0 = 2 \times 10^{-21} L^{5/2}, \mathcal{E}_0 = 3 \times 10^{-48} L^{8.5} \quad (20)$$

Comparison of the results in equation (20) with that in equation (6) shows that the total energy of the relativistic electrons present in the flare at any one time is

$$\mathcal{E}_{\text{rel}} = \mathcal{N}_0 \gamma_0 mc^2 = 10^{66} L^{-15/4} \quad (21)$$

It is obvious that $\mathcal{E}_{\text{rel}} < \mathcal{E}_0$, because the electrons derive their energy from the magnetic field. A lower limit to the linear dimensions of the flare is therefore given by

$$L \geq 1.7 \times 10^9 \text{ cm} \quad (22)$$

When there is equality in equation (22), \mathcal{E}_0 equals 1.6×10^{31} erg, barely enough to account for the visual energy output of the flare. If \mathcal{E}_0 exceeds \mathcal{E}_{rel} , for instance $\mathcal{E}_0 = \alpha \mathcal{E}_{\text{rel}}$ with $\alpha > 1$, then

$$L = 1.7 \times 10^9 \alpha^{0.08} \text{ cm} \quad (23)$$

so that even with $\alpha = 100$, say, the estimate for L is raised by only a factor 1.5. Furthermore, because \mathcal{E}_{rel} decreases as L increases, it seems most probable that \mathcal{E}_{rel} can never be as large as the total visual energy output of the flare, and that the synchrotron lifetime of the electrons is shorter than the duration of the flare. It must therefore be possible for electrons to pick up energy from the magnetic field as the flare evolves.

In the light of all these arguments it seems reasonable to conclude that $L \sim 2.5 \times 10^9$ cm. This implies that $\mathcal{E}_0 = 3.0 \times 10^{32}$ erg, $H_0 = 600$ gauss, $\mathcal{E}_{\text{rel}} = 6.0 \times 10^{30}$ erg, $\gamma_0 = 640$ and

$\mathcal{N}_0 = 1.0 \times 10^{34}$. The height h_1 equals 1.4×10^{10} cm and the estimate for the density in the lower corona becomes $\rho_0 = 3.8 \times 10^{-13} \text{ g cm}^{-3}$.

By the time the magnetised bubble reaches height h_1 it has expanded by a factor 5.6 in linear dimensions, and the magnetic field strength has dropped, by a factor of 1/31, to 20 gauss. If the radiation at 408 MHz also results from synchrotron emission, the energy $\gamma_1 mc^2$ of the electrons is then given by

$$\omega_{c,1} \approx 2.5 \times 10^9 = \gamma_1^2 e H / mc = 3.4 \times 10^8 \gamma_1^2$$

$$\text{or } \gamma_1 \sim 3$$

The observed output of the radio flare at its peak is 10 flux units (f.u.) $= 10^{-22} \text{ erg cm}^{-2} \text{ Hz}^{-1} \text{ s}^{-1}$. The distance to UV Ceti is 2.7 pc or 8×10^{18} cm and therefore the rate of output of energy by the star, per unit frequency interval, is $8 \times 10^{16} \text{ erg Hz}^{-1} \text{ s}^{-1}$, or about $3.2 \times 10^{25} \text{ erg s}^{-1}$, assuming a bandwidth of about 400 MHz. This means that there must be \mathcal{N}_1 electrons radiating, where

$$\mathcal{N}_1 \gamma_1^2 (e^4 H^2 / m^2 c^3) = (e^3 / mc^2) \mathcal{N}_1 H_1 \omega_{c,1} = 3.2 \times 10^{25}$$

There seem to be more relativistic electrons radiating during the radio phase of the flare than there were during the earlier, visual phase. But their individual energies are smaller, and their total energy at any one time is 4.0×10^{31} erg, about seven times that during the optical flare. For comparison, the magnetic energy in the bubble is now $\mathcal{E}_0 L/h_1 = 5.4 \times 10^{31}$ erg, still considerably larger than the particle energy. The acceleration process evidently still feeds energy to the electrons in the later stages of the flare.

The model of the flare has implications for the stellar wind. Take $r_s = 3R$ or $4R$ as possible values for the sonic radius. They correspond to

$$a = (GM/2r_s)^{1/2} = 1.7 \times 10^7 \text{ cm s}^{-1} \text{ or } 1.5 \times 10^7 \text{ cm s}^{-1}$$

and to temperatures $T = \bar{m} a^2 / k = 2.2 \times 10^8 \text{ K}$ or $1.6 \times 10^8 \text{ K}$. With the approximate form for the density variation in the stellar wind, the density at $r = r_s$ becomes $\rho_s = 1.4 \times 10^{-14} \text{ g cm}^{-3}$ or $6 \times 10^{-15} \text{ g cm}^{-3}$, and the predicted rate of mass loss

$$4\pi r_s^2 \rho_s a = 5 \times 10^{14} \text{ g s}^{-1} \text{ or } 3.4 \times 10^{14} \text{ g s}^{-1}$$

These values are not sensitive to the assumed value of r_s . They are of the same order as the mass loss rate inferred for another flare star, YZ CMi (ref. 4).

It is not obvious, with an isothermal model, how the amount of energy carried off by the stellar wind should be estimated, for in principle the wind speed keeps increasing indefinitely with distance. In practice, though, the isothermal condition is bound to fail at some reasonable distance. An acceptable first estimate is that each gram of stellar wind carries away energy of about $GM/R = 1.8 \times 10^{15} \text{ erg g}^{-1}$, and the total predicted energy loss into the wind is of the order of $8 \times 10^{29} \text{ erg s}^{-1}$. For comparison the luminosity of the quiescent star is $1.0 \times 10^{30} \text{ erg s}^{-1}$. The present model thus requires that a large fraction, at least 40%, of the energy brought by convection to the photosphere should later become available as mechanical energy for heating the stellar corona.

Finally, the magnetic energy stored in the region of the flare amounts to $\mathcal{E}_0 = 3.0 \times 10^{32}$ erg, localised above an area $L^2 \sim 6 \times 10^{18} \text{ cm}^2$ of the star. A supply of about $4 \times 10^9 \text{ erg cm}^{-2} \text{ s}^{-1}$ seems to be available as mechanical energy to drive the stellar wind. With an equal supply available to twist up the lines of force it would only take about $1.3 \times 10^4 \text{ s}$ (about 3.5 h) to charge up the magnetic field, ready for the flare.

I thank Sir Bernard Lovell for telling me about the observations of UV Ceti, and for discussion about its properties.

Redshifts of 1548 + 115a and 1548 + 115b in the theory of the generalised gravitational potential

In a recent communication Wampler *et al.*¹ reported the redshifts of the QSO pair 1548 + 115a, b. For the QSO 1548 + 115a the redshift is given as $z = 0.4359$ and for 1548 + 115b as $z = 1.901$. Since these QSOs are separated by approximately 5 arc s these authors concluded, primarily on the basis of a statistical argument, that these two objects are at the same cosmological distance and that the redshifts are therefore "discordant". In addition these authors noted that the wavelength ratio $(1 + z)_b / (1 + z)_a = 2.02$, which is sufficiently close to a factor of two for them to speculate that for such optically associated objects this "... is either an unfortunate coincidence or a profound mystery".

Stellar objects that are apparently connected but have considerably different redshifts have been reported previously. Arp², for example, has reported on pairs of galaxies which are joined by luminous bridges but which have different galaxy redshifts, and Burbidge *et al.* (BBSS)³ have published a statistical analysis of the proximities of 47 QSOs to bright galaxies, concluding that four of these QSOs were probably associated with their respective galaxies. Again in the Burbidge work the redshifts for the pairs are "discordant".

The work of Arp and BBSS has been discussed previously^{4,5} within the context of the generalised gravitational potential which is inferred from my general relativistic scalar field theory in the complex Weyl space⁶. In this theory the macroscopic theories of Einstein gravitational and Maxwell electromagnetism are united together with the microscopic scalar field in Ψ . When this theory is applied to the "Schwarzschild" problem for the nucleus, where the Newton-Einstein constant is negligible, the integration constant in the component g_{00} of the metric tensor is identified with a nuclear property, namely the nuclear core radius. Therefore for a stellar object with a density comparable with that of nuclear matter, where both constants are significant

$$g_{00} = 1 - ([2GM/c^2] + r_0 A^{1/3})/r \quad (1)$$

where G is the Newtonian gravitational constant, M the mass of the body, c the speed of light, r_0 the nucleon core radius and A the stellar mass number. The generalised gravitational redshift now becomes

$$z_G = [(2R_0 R/r_0 \rho^{1/3} (1 + R)) - 1]^{-1} \quad (2)$$

where

$$R = (r_0 c^2 / 2G m^{1/3}) M^{-2/3} \quad (2a)$$

and m is the nucleon mass, $R_0 = 1.21$ fm the nucleon radius and $\rho = D/D_0$ is the ratio of the density D of the stellar body to that of the density D_0 of the nucleon. Because of the "Schwarzschild" singularity we must also have in this theory that $z_G < 1$. And for a total redshift of z

$$z_v = (z - z_G / (1 + z_G)) \quad (3)$$

where z_v is the recessional redshift.

If we now apply the theory of the generalised gravitational potential to the pair 1548 + 115a, b and assume a negligible gravitational factor for 1158 + 115a (that is an object with both a negligible contribution from Einstein gravitation and a density much less than that of nuclear matter), we have $z_v = z = 0.4359$. If in addition we assume the maximum possible gravitational contribution from this theory ($z_G \approx 1$) we obtain from equation (3) $z_v \approx 0.451$ for 1548 + 115b; thus there is no need, in the context of this theory, to seek a further explanation of the wavelength factor of ~ 2 commented on by Wampler *et al.*

Stated in an alternative way, we assume that the total redshift given by Wampler *et al.* for 1548 + 115a represents the recessional redshift for both objects. In addition, however, we apply equation (3), utilising the maximum possible gravitational redshift from this theory ($z_G \approx 1$) for 1548 + 115b and obtain $z \approx 1.8718$ for 1548 + 115b, which is close to the result obtained by Wampler *et al.*

If the work⁷ of Cameron on neutron stars, which does not make use of equation (1), is nonetheless taken as a model for all stellar objects with neutron densities then the masses of these objects are of the order of one solar mass. It should be noted from equation (2) that gravitational redshifts in this theory can be appreciable for small masses. For example, for a solar mass with nuclear density ($\rho = 1$), $z_G = 0.776$. To account, therefore, for the energetics implied by the data on 1548 + 115b it has been suggested to me by Dr Howard Poss of Temple University that perhaps 1548 + 115b is actually an assemblage of such stars. This suggestion is, however, not to be restricted to the pair 1548 + 115a, b but must be generalised to any stellar system whose energetics cannot be sustained by a constraint of one solar mass, which is indeed how this general concept is applied in this theory for any stellar system with a "discordant" redshift. In addition, if cognisance is to be taken of the precision in the redshift calculations by Wampler *et al.* then one could postulate a small relative velocity between 1548 + 115a and 1548 + 115b with a resultant velocity component in the direction of the Earth for 1548 + 115a. This is a more definitive statement than that offered by these authors when discussing the precision of their measurements. Furthermore, if these authors mean by "spectral peculiarities" that there could exist associated QSO pairs with different redshifts not explainable on the basis of Einstein's theory and that therefore "... no pre-existing theory suggested them ...", then this statement is incorrect^{4,6}.

Both Bahcall *et al.* (BMB)⁸ and Hazard and Sanitt (HS)⁹ have pursued the work of BBSS by choosing different sample spaces. In the former case these authors considered a larger group of quasars in addition to the 3C quasars chosen by BBSS. Although they found additional quasars that are closer to bright galaxies than expected if these two types of objects were uncorrelated, the increase was not at all proportional to the BBSS finding. In this connection it should be noted that, from the point of view of the generalised gravitational potential, only three (3C232, 3C275.1, 3C309.1) of the original four in the BBSS list were consistent with a connection hypothesis, whereas the fourth (3C268.4) was not; that is to say that this theory predicts that observational data may be found to support the connection hypothesis for the first three quasars but no observational data will be found to establish a physical connection between 3C268.4 and NGC4138. If this theory were further taken into account then the original BBSS number would change from four to three probable associations. This in turn would modify somewhat the expectations of the work of BMB.

The latter work of HS also failed to confirm the BBSS results (restricted to 3CR types) when source and galaxy lists, other than those chosen by BBSS, were used. It should be noted that the elimination of 3C232 from the BBSS list would modify still further the expectations of BMB.

In an additional discussion Bahcall and Woltjer¹⁰ considered the pairs Ton 155, 156 and 1548 + 115a, b. They conclude that, when taken as a class, the close proximity of QSOs in each pair "may be comfortably explained as random coincidences ...".

The problem with all four papers quoted here^{3,6-10} that adopt a statistical approach to the redshift problem is that they each select (*a priori*) a subset of objects. The central physical problem, however, is whether or not there is an additional component in the redshift. The theory of the generalised gravitational potential claims there is, and to this end galaxy-galaxy pairs, QSO-galaxy pairs and QSO-QSO pairs should be examined with continually improved observational techniques, where the statistical analyses are of value only with respect to the choice of areas for concentrated observational effort. The question of whether or not QSOs are local or cosmological or consist of

both types of object will in any event obviously be influenced strongly by observational results obtained on the redshift problem.

I am particularly indebted to Professor Howard Poss of Temple University for many discussions on the material of this paper.

Infrared heterodyne spectroscopy of CO₂ on Mars

THERE has been considerable interest in applying infrared heterodyne techniques to astronomical problems¹⁻³. We have used an infrared heterodyne spectrometer operating near 11 μm with a resolving power of 1.5×10^6 to obtain spectral line profiles of carbon dioxide absorption in the Martian atmosphere. The multichannel system determined shapes of three lines in the $10^0\ 0-00^0\ 1$ vibration-rotation band of $^{13}\text{C}^{16}\text{O}_2$, and found equivalent widths about 50 MHz ($0.0017\ \text{cm}^{-1}$). A lower limit of 670 MHz ($0.022\ \text{cm}^{-1}$) on the equivalent width of the P(20) line of $^{13}\text{C}^{16}\text{O}_2$ was also obtained.

Figure 1 shows a block diagram of the equipment. Two concave mirrors not shown in Fig. 1 matched the diameter and wavefront curvature of the laser and telescope beams at the combining beam splitter. The 9% of the laser beam which was reflected by the beam splitter and the 91% of the telescopic beam which was transmitted were focused on to a copper-doped germanium photomixer cooled to 4 K. The photomixer signals were amplified over a frequency band from 100 to 1,500 MHz and fed into a radiofrequency mixer with a variable local oscillator frequency. The output of the mixer was fed into a filter bank which simultaneously measured the power in eight channels, each 18 MHz wide, equally spaced from d.c. to 150 MHz. Each channel had a synchronous detector locked to the chopping frequency and followed by a low pass filter. The eight outputs of the filter bank were sampled and digitised by computer. To cancel offsets between the two parts of the sky seen by the dual beam chopper, the planet was periodically alternated from one beam to the other.

As a periodic calibration of the system sensitivity, a black body at 500 K was placed in front of the chopper. By placing the heliostat in autocollimation, the telescope transmission was found to be 0.85. Atmospheric transmission was determined by measuring heterodyne signals from the Moon and Mars as a function of zenith angle. Averaged over the band of 100 to 1,000 MHz, the zenith transmission on the P(20) line of $^{13}\text{CO}_2$ (wavelength $10.57\ \mu\text{m}$) was 0.45, lower than may be expected from previous measurements⁴

Fig. 1 Block diagram of the equipment located at the auxiliary solar telescope, located near the focal plane. *a*, Guiding eyepiece; *b*, black body; *c*, chopper; *d*, beamsplitter; *e*, CO₂ laser; *f*, germanium: copper photomixer; *g*, amplifier; *h*, radiofrequency local oscillator; *i*, radiofrequency mixer; *j*, eight channel filter bank; *k*, computer. The telescope consists of a steerable flat heliostat with a collecting area of about 0.4 m², followed by a fixed off-axis focusing mirror and three flat mirrors which direct the beam to the equipment. A rotating mirror in the focal plane of the telescope chopped the source against a sky background at 150 Hz. A linearly polarised laser used as an infrared local oscillator was operated in the TEM₀₀ mode, and stabilised on various rotational transitions of the $10^0\ 0-00^0\ 1$ band of CO₂.

and transmission of the $^{13}\text{CO}_2$ lines near $11.2\ \mu\text{m}$ was 0.90. The approximate standard deviation in each case was 0.05. The contribution of water vapour to the absorption was estimated to be 0.05 to 0.10 (ref. 5). The system sensitivity for each 18 MHz channel was thus calculated to be $5 \times 10^{-22}\ \text{Wm}^{-2}\ \text{Hz}^{-1}$ at the top of the Earth's atmosphere, assuming operation on a $^{13}\text{CO}_2$ line, radiation of one polarisation, and a signal to noise ratio of unity for one second of integration. Because of the antenna properties of the heterodyne receiver⁶ and the shape of the heliostat mirror, the system was only sensitive to radiation in an elliptical beam measuring 4 arc s in declination (dec) and 3 arc s in right ascension (RA). The angular diameter of Mars was about 14 arc s at the time of observation.

In order to understand how the spectral information was obtained it is necessary to consider how the spectrum was folded on itself in the two mixing operations (Fig. 2). The continuum infrared radiation is folded over into the absorption profile and decreases the fractional depth by a factor

of two. We assumed that the absorption lines were symmetric and tuned our radio frequency local oscillator to the expected centre of the absorption line. This frequency was calculated from the relative velocities and rotation rates of Earth and Mars, and typically had a value near 1,100 MHz. The output of the radio frequency mixer thus represents the amplifier output power folded about the frequency at line centre of the radio frequency local oscillator. This is quite accurate for the $^{13}\text{CO}_2$ lines because their widths are considerably less than both the velocity shift and the width of the entire filter bank. The $^{12}\text{CO}_2$ line, however, is very broad and its interpretation is more difficult.

In a computer simulation of the Martian atmosphere we assumed an atmosphere of 100% carbon dioxide consisting of plane-parallel layers of constant temperature and pressure (Fig. 3). The rate of change of temperature with altitude is conventionally defined as the lapse rate, and the height at which the pressure drops by a factor of e is similarly defined as the scale height. We assumed a constant lapse rate and a scale height, at the surface, of 11 km. Parameters used in the simulation were:

T_s = surface temperature (given separately for each line in Fig. 3);

$\Delta T_{AS} = T_s$ minus the temperature of the atmosphere at the surface;

Γ = temperature lapse rate (degrees km^{-1});

P_s = surface pressure (mbar).

In addition we defined the parameter

$$z = [P_s/6 \text{ mbar}] \cdot R(13/12) \cdot A(13/12).$$

This is proportional to the number of $^{13}\text{CO}_2$ molecules in the atmosphere and to the transition rate, where

$R(13/12)$ = ratio of isotopic species by number and

$A(13/12)$ = ratio of Einstein A coefficients for equivalent lines in the two isotopic species.

The best values of Γ , ΔT_{AS} , and z each depend to a large extent on which values are taken for the other two parameters (Table 1). This is because the number of absorbing molecules and their average temperature must remain nearly fixed in order to maintain the same absorption profile for each model. Four sets of these parameters which give equally good fits to the data are given in Table 1. Model 1 (Table 1) uses the adiabatic lapse rate for Mars. Higher lapse rates would be quickly reduced to the adiabatic case by convection. Model 4, with zero lapse rate, is physically unrealistic but is included to show that z does not continue to decrease as the lapse rate further decreases. The results themselves do not put upper bounds on ΔT_{AS} and z ; values for z which fit the data are, however, in all cases larger than expected and values of ΔT_{AS} were therefore chosen so as to minimise z .

Statistical errors in the data produce uncertainties in the model. The standard deviation of T_s is about 1.5 K for the P(16) line and about 3.0 K for P(22) and P(26); systematic errors in the calibration cannot, however, be completely ruled out. The value of T_s is obtained from the black body calibration. Based on this calibration our measurement of the lunar flux is about 15% higher than the published value and has a standard deviation of 3% but the discrepancy is, at least in part, because of imprecise knowledge of the Sun angle at the point observed. In any case the discrepancy is in the direction which, if corrected for, would reduce our measured flux from Mars and lower the surface temperature. The correlations between Γ , ΔT_{AS} , and z make uncertainties in these quantities difficult to estimate, but the errors are considerably smaller than the range allowed from model to model. For example, the standard deviation of z in Model 3 for the P(16) line is about 0.004 if Γ and ΔT_{AS} are kept fixed.

Previous data⁷ can be compared with the parameters we have fitted to our data. The effective continuum temperature near the $^{13}\text{CO}_2$ lines is about 250 K (Fig. 3). Mariner 9 (ref. 7), looking at the sub-solar point as we did, obtained

a temperature near 11 μm of about 260 K. Mariner 9 also measured a temperature lapse rate of 2.5 K km^{-1} and an atmospheric temperature at the surface about 25 K cooler than the surface itself. These values are close to those used in Model 2 (Table 1). The parameter z is of particular interest because our data indicate a higher value than expected in all models. Some limits can be placed on the ranges of the three factors comprising z . Mariner 9 reported a surface pressure of 6 mbar with a range from 4 to 8 mbar because of terrain changes. Our results place an upper limit of 12 mbar because at this pressure the effects of collisional line broadening would have become apparent. A value of 0.24 s^{-1} was taken for the Einstein A coefficient of $^{13}\text{CO}_2$ (refs 8,9). The correct value for $^{13}\text{CO}_2$ may, however, be somewhat different because this coefficient is strongly influenced by the Fermi resonance between the lower level of the absorbing transition and the 020 vibrational level. Even a small change in the mass of the carbon atom affects the strength of this interaction. Measurements of the relative output power of carbon dioxide lasers operating on the two isotopic species suggest that the ratio $A(13/12)$ is about 2/3 (C. Freed personal communication). Taking a value for surface pressure of

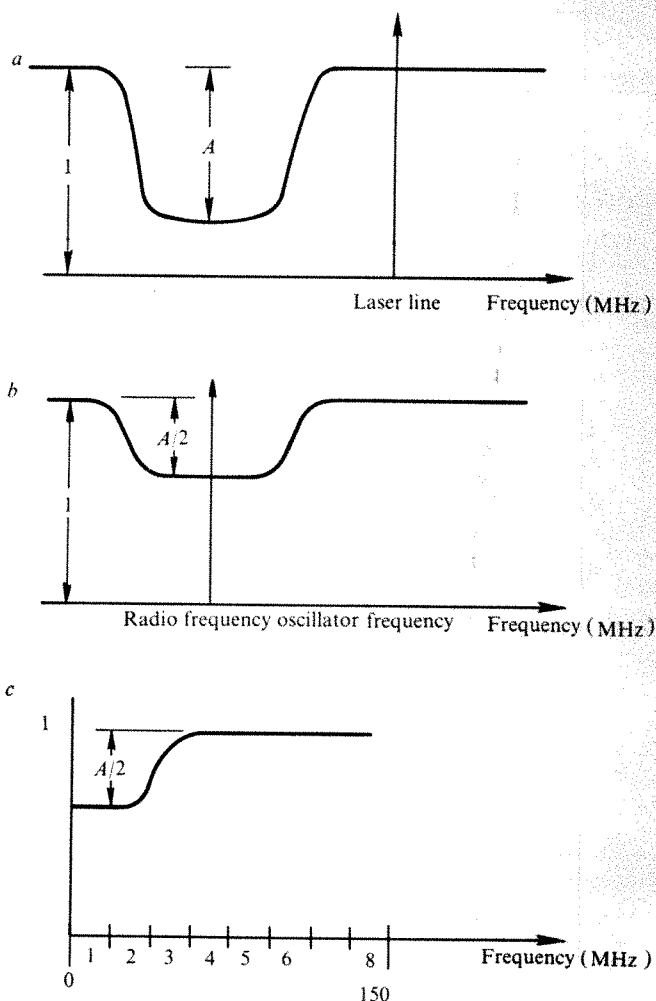

Fig. 2 Folding of the absorption line because of mixing: a, schematic representation of a Martian infrared absorption line shifted in frequency from a laser line of the same molecular transition by the relative motion of Earth and Mars. A is the fractional depth of the absorption. Infrared frequencies equally spaced on either side of the laser line appear at the same place in the radiofrequency spectrum of the amplifier output; b, the absorption line as it appears at the amplifier; c, the absorption line as it appears at the mixer output. The numbers along the abscissa represent the eight channels of the filter bank into which the mixer output is fed.

6 mbar, the terrestrial value of 0.011 for $R(13/12)$, and assuming a value of 2/3 for $A(13/12)$, gives a value of 0.007 for z , a number about three times smaller than those in Table 1 which fit our present measurements. The cause of this discrepancy is not clear.

Because $^{12}\text{CO}_2$ was expected to be 90 times more abundant than $^{13}\text{CO}_2$, we made the $^{12}\text{CO}_2$ measurements first. The results, however, were not as significant as those for $^{13}\text{CO}_2$. Because of the large width of the $^{12}\text{CO}_2$ line, measurements were made in bands 150 MHz wide distributed from 550 MHz below to 350 MHz above the expected frequency of the line centre. The bands could not be measured simultaneously because a suitably wide filter bank was not available. The measured flux was independent of frequency to within a standard deviation of 20%, indicating a line broader than the frequency range examined. The data are consistent with a continuum of 250 K folded into an absorption line with a flux of less than $2 \times 10^{-23} \text{ W Hz}^{-1}$ (200 K) and an equivalent width greater than 670 MHz (0.022 cm^{-1}). A computer simulation using a lapse rate of 2.5 K km^{-1} , a value for ΔT_{AS} of 30 K, and a surface pressure of 6 mbar predicts an equivalent width of 400 MHz for the $^{12}\text{CO}_2$ line. The difficulties of accurate cali-

Table 1 Parameters for computer simulation			
Model	Γ	ΔT_{AS}	z
1	5 K km^{-1}	25 K	0.027
2	2.5 K km^{-1}	30 K	0.02
3	1.3 K km^{-1}	35 K	0.017
4	0 K km^{-1}	45 K	0.02

bration mean that the discrepancy is probably not significant, although its direction is similar to that found for $^{13}\text{CO}_2$, corresponding to excess absorption.

The results demonstrate that infrared heterodyne spectroscopy can be used in astronomy for spectral resolution exceeding by several orders of magnitude that obtained with conventional techniques, although the copper-doped germanium photomixer used had a sensitivity about 25 times less than the theoretical limit of $2 \times 10^{-20} \text{ W Hz}^{-1}$ for heterodyne detectors at 11 μm . Continuously tunable infrared lasers would allow high resolution of lines anywhere in the infrared band and perhaps the detection of absorption lines of interstellar gas against bright sources.

We thank Professors C. H. Townes and R. Y. Chiao for helpful discussion and Dr. A. K. Pierce and the staff of the Solar Division of Kitt Peak National Observatory. This work was partially supported by NASA.

Fig. 3 Data obtained for the P(26) a, P(16) b, and P(22) c, rotational lines of $^{13}\text{CO}_2$. In a, $I_s=256 \text{ K}$, and equivalent width=50 MHz; b, $I_s=250 \text{ K}$, and equivalent width=66 MHz; c, $I_s=246 \text{ K}$, and equivalent width=49 MHz. The original data has been unfolded and plotted in the format of Fig. 2a as half of an infrared line. The ordinate is received spectral power in W Hz^{-1} divided by Boltzman's constant k and referenced to the top of the Earth's atmosphere. Absolute temperatures for black bodies of equal spectral radiance are shown at the right of the figure. Error bars represent plus and minus one standard deviation and correspond closely to predictions of the theory of heterodyne mixing¹⁰. The abscissa MHz is measured from the expected position of line centre. The P(26) and P(22) lines each represent about 1 h of observation, the P(16) line about 2 h. The solid curves represent absorption line profiles calculated in a computer simulation of the Martian atmosphere (see text).

Petrogenetic implications of argon isotopic evolution in the upper mantle

THE construction of models for the isotopic evolution of terrestrial argon (unlike those for strontium and lead¹⁻³), has been severely hampered by the fact that there are to our knowledge, no reported studies of the initial argon isotopic ratios in rocks of various ages. It has been estimated³ that the cosmic abundances of the stable argon isotopes are ^{40}Ar , 0.4%; ^{38}Ar , 14.1%; and ^{36}Ar , 85.6%. This gives a cosmic $^{40}\text{Ar}/^{36}\text{Ar}$ ratio of 0.005, which may reasonably be assumed to approximate closely the initial $^{40}\text{Ar}/^{36}\text{Ar}$ ratio in the solid Earth at the time of formation.

The reported abundances of the argon isotopes in the terrestrial atmosphere⁴ at present are ^{40}Ar , 99.600%; ^{38}Ar , 0.063%; and ^{36}Ar , 0.337%, giving an atmospheric $^{40}\text{Ar}/^{36}\text{Ar}$ ratio of 295.5. This anomalous situation is clearly related to the production of radiogenic ^{40}Ar derived from the natural decay of ^{40}K in the Earth's crust and mantle. An increase of

more than four orders of magnitude over the initial terrestrial $^{40}\text{Ar}/^{36}\text{Ar}$ ratio is indicated.

To demonstrate the isotopic evolution of argon in the solid Earth, we calculated the initial $^{40}\text{Ar}/^{36}\text{Ar}$ ratios retained in analysed suites of mantle-derived igneous rocks, both volcanic and plutonic, of different ages (Table 1). The initial $^{40}\text{Ar}/^{36}\text{Ar}$ ratios were calculated in a manner exactly analogous to the determination of initial $^{87}\text{Sr}/^{86}\text{Sr}$ ratios, the intercept of an argon isochron following the linear equation:

$$(^{40}\text{Ar}/^{36}\text{Ar})_{\text{total}} = [\lambda_e/(\lambda_e + \lambda_B)](^{40}\text{K}/^{36}\text{Ar})(\exp(\lambda t) - 1) + (^{40}\text{Ar}/^{36}\text{Ar})_{\text{initial}}$$

A plot of the initial $^{40}\text{Ar}/^{36}\text{Ar}$ ratios obtained from eighteen suites of mantle-derived samples against their time of emplacement or extrusion (Fig. 1) strongly suggests that there has been an increase in the initial $^{40}\text{Ar}/^{36}\text{Ar}$ ratio with time. This we interpret as evidence for a significant increase in the $^{40}\text{Ar}/^{36}\text{Ar}$ ratio in the mantle over the past 800 Myr.

Implicit in this interpretation is the assumption that a significant proportion of the ^{36}Ar observed in the mass spectrum of argon extracted from terrestrial rocks and minerals is derived from the source region of the analysed samples and does not represent an atmospheric contaminant. We are supported in this contention by reported analyses of lava flows⁵⁻⁸ which have shown that most of the so-called ^{36}Ar 'contamination' comes not from the extraction line but is contained within the rocks themselves and is released along with ^{40}Ar during fusion. The initial $^{40}\text{Ar}/^{36}\text{Ar}$ ratios preserved in igneous rocks seem therefore to be representative of the $^{40}\text{Ar}/^{36}\text{Ar}$ ratios in the source region of the parent magmas. The $^{40}\text{Ar}/^{36}\text{Ar}$ ratio in any source region will increase with time at a rate dependent on the concentrations of potassium and ^{36}Ar , and the rate of argon release to the atmosphere.

Analyses of historically erupted lava flows^{5,6,8}, indicate initial $^{40}\text{Ar}/^{36}\text{Ar}$ ratios ranging from 282.9 to 350.0. Measured ratios greater than the present-day atmospheric ratio have been explained by the inclusion of xenoliths and xenocrysts in the analysed whole-rock samples but a satisfactory explanation has not been given for the lower ratios. The possibility of diffusion and fractionation of atmospheric argon into the cooling lava⁸ does not seem realistic to us. This variation of the observed $^{40}\text{Ar}/^{36}\text{Ar}$ ratios in modern volcanic rocks may be due to inhomogeneities in the upper mantle or to remelting of older gabbroic rocks in layer 3 as suggested for some Icelandic rocks⁹. We therefore conclude, from the reported analyses of modern basalts, that the average $^{40}\text{Ar}/^{36}\text{Ar}$ ratio in the upper mantle is at present not greater than the atmospheric ratio (295.5) and possibly a little lower.

A similarity between the $^{40}\text{Ar}/^{36}\text{Ar}$ ratio in the upper mantle and the terrestrial atmosphere leads us to the conclusion that it is the Earth's mantle, not the crust, that is the major source of atmospheric argon. Despite the obvious generation of radiogenic ^{40}Ar in the potassium-rich crust of the Earth, there is little evidence that significant outgassing of crustal argon is occurring today. It has been variously suggested (see Rankama¹⁰, for a summary) that the ^{40}Ar present in the Earth's atmosphere has been gradually released from crustal rocks throughout geological time as a result of weathering processes¹¹ or volcanism¹². Alternative models involving major degassing of the crust and mantle during the first 10^9 years of the Earth's history have been suggested by Nicolet¹³ and Damon and Kulp¹⁴, while Turekian^{15,16} and Schwartzman¹⁷ advocated continuous transfer of argon from both the crust and mantle. Modern plate tectonic theory provides a viable mechanism for the continual release of argon from the mantle, by way of

Fig. 1 Variation of the initial $^{40}\text{Ar}/^{36}\text{Ar}$ ratio in the upper mantle-derived igneous rocks over the past 800 Myr. This variation is considered to reflect the variation in argon isotopic ratio of the upper mantle region with time.

volcanism on active plate boundaries, but there is no simple mechanism available for the release of argon accumulating in the Earth's crust. Furthermore, a large component of crustal argon in the atmosphere would result in a present-day atmospheric $^{40}\text{Ar}/^{36}\text{Ar}$ ratio much greater than 295.5.

It is generally assumed that minerals melting and recrystallising in the Earth's crust under igneous and metamorphic conditions will lose argon to the atmosphere as a result of temperature-controlled diffusion processes. In reality, what is more likely to occur under these conditions is lattice diffusion and isotopic homogenisation of argon, with effective retention in the whole-rock system, a situation analogous to strontium isotopic homogenisation under similar conditions. Very little argon would escape from the crust directly to the atmosphere, except perhaps along major fracture zones. Homogenisation of the argon isotopes would have the effect of equalising the $^{40}\text{Ar}/^{36}\text{Ar}$ ratio in the whole-rock system, so that initial $^{40}\text{Ar}/^{36}\text{Ar}$ ratios measured in crustal rocks should be greater than the present-day atmospheric ratio. Excessively high initial ratios have been recorded in metamorphic rocks, expressed in terms of an 'excess' ^{40}Ar concentration¹⁸⁻²¹.

To test our conclusions we have made a semiquantitative analysis of the available data. Any relevant calculations suffer, of course, from uncertainties in the estimation of potassium abundances^{22,23} in the Earth (Table 2). The calculated mass of radiogenic ^{40}Ar produced in the Earth from the decay of ^{40}K consequently has a large error which is propagated through the calculations.

The mass of ^{40}Ar produced in the Earth is calculated assum-

Table 2 Estimate of potassium and radiogenic argon in the Earth

	Mass of shell ²⁴ ($\times 10^{21}$ tons)	Potassium ^{22,23} K % ($\times 10^{15}$ tons)	Radiogenic ⁴⁰ Ar ($\times 10^{15}$ tons*)
Crust	0.024	320 \pm 55	1.350
Mantle and core	5.941	500 \pm 200	0.008
Total	5.965	820 \pm 207	0.014
Pyrolite	0.441	500 \pm 200	0.108
		(ref. 25)	0.0668 \pm 0.0267
Atmosphere			0.0653 (ref. 11)

* ⁴⁰Ar calculated from the potassium abundances with an age of 4,500 Myr for the Earth.

ing the Earth to be 4,500 Myr old. The observed mass of ⁴⁰Ar in the atmosphere (0.065×10^{15} tons), compared to the calculated mass of radiogenic ⁴⁰Ar produced in the Earth (0.11×10^{15} tons), suggests that only 60% of all the ⁴⁰Ar produced in the Earth has been released to the atmosphere.

In calculating the mass of ⁴⁰Ar in the mantle we make the following assumptions: (1) All ⁴⁰Ar in the atmosphere is derived from the solid Earth. (2) The upper mantle and crust are separate systems with respect to argon isotopic evolution. (3) Sediments make up approximately 5% of all crustal material²⁴, therefore not more than 5% of crustal argon has been released to the atmosphere and perhaps as little as 1% (ref. 10).

From assumption (3), taking 5% of crustal ⁴⁰Ar as being the maximum released to the atmosphere, the balance of the ⁴⁰Ar in the atmosphere is assumed to have come from the mantle, so (in units of 10^{15} tons):

$$\begin{aligned} \text{⁴⁰Ar in atmosphere} &= (0.0653 \pm 0.0033) \\ \text{⁴⁰Ar released from crust (5\%)} &= (0.0021 \pm 0.0004) \\ \therefore \text{⁴⁰Ar released from mantle} &= (0.0632 \pm 0.0034) \\ \therefore \text{⁴⁰Ar remaining in mantle} &= (0.0036 \pm 0.0269) \end{aligned}$$

The large error in the estimation of ⁴⁰Ar remaining in the mantle arises because the abundance is the difference between two nearly equal and poorly known numbers.

For purposes of calculation, we now assume that: (4) All the potassium, and thus radiogenic ⁴⁰Ar, is concentrated in an upper mantle region with a pyrolite²⁵ composition. (5) This pyrolite layer is approximately 200 km thick and has a mass of 0.441×10^{21} tons (Table 1). (6) The argon isotopic composition is homogeneous throughout the pyrolite layer.

The maximum concentration of ⁴⁰Ar at present in this pyrolite layer can now be calculated knowing the mass of the layer and the mass of ⁴⁰Ar remaining in the upper mantle. Thus the maximum ⁴⁰Ar concentration in the total pyrolite layer is $(8.2 \pm 61.0) \times 10^{-3}$ p.p.m. ⁴⁰Ar.

The present-day ³⁶Ar concentration in the upper mantle can be estimated from the observed ³⁶Ar concentrations in modern volcanic rocks derived from the mantle. The concentration of ³⁶Ar in young volcanic rocks, measured in our laboratory, after correcting for line blank, is estimated to be $(2.4 \pm 1.1) \times 10^{-3}$ p.p.m. ³⁶Ar. Because these rocks have been at least partially outgassed on extrusion, this value serves at least as a minimum concentration for the ³⁶Ar in the upper mantle source region.

Assuming that the present-day ⁴⁰Ar/³⁶Ar atomic ratio in the upper mantle source region is 295 ± 10 (or 327 weight ratio), then the present-day ⁴⁰Ar concentration in the upper mantle is at least $(7.8 \pm 3.6) \times 10^{-3}$ p.p.m. ⁴⁰Ar. This value is close to that estimated in the pyrolite layer by the difference method. This near coincidence could be due to the cancelling out of the different assumptions (1) to (6), or it might indicate that Hurley's potassium abundances^{22,23} are more precise than indicated in Table 2 and that most of the ⁴⁰Ar at present in the atmosphere has been released from the mantle.

According to our model, approximately 95% of all the ⁴⁰Ar produced in the mantle has been lost to the atmosphere. At least that percentage of ³⁶Ar must also have been lost, assuming no isotopic fractionation. From assumptions (5) and (6), using the observed concentration of ³⁶Ar in mantle-derived volcanic rocks, the mass of ³⁶Ar in the pyrolite shell (200 km thick) is estimated to be $(1.05 \pm 0.50) \times 10^{10}$ tons at present.

This must represent at most 5% of the ³⁶Ar originally present in the mantle. Therefore, 4,500 Myr ago, the mass of ³⁶Ar in the mantle was at least $(21.0 \pm 9.0) \times 10^{10}$ tons. There is at present 20.0×10^{10} tons of ³⁶Ar in the atmosphere, so it is quite reasonable to postulate that the majority of ³⁶Ar in the atmosphere has also come from the mantle.

Protocrustal material, with an average potassium concentration of 1.350%^{22,23}, would yield in 4,500 Myr a concentration of ⁴⁰Ar ten times greater than that in the upper mantle. The net result of this would be to give ⁴⁰Ar/³⁶Ar ratios in the deep crust that are an order of magnitude greater than the ⁴⁰Ar/³⁶Ar ratio in the upper mantle.

Initial ⁴⁰Ar/³⁶Ar ratios on igneous rocks which have not undergone isotopic homogenisation since crystallisation should yield information about the source region. It is thus possible to distinguish clearly between partial melting in a low potassium environment (such as the upper mantle) and partial melting of old sialic material. Initial ⁴⁰Ar/³⁶Ar ratios should also be very sensitive to any geological contamination (assimilation) of a basaltic magma by older potassium-rich material.

In summary: (1) Initial ⁴⁰Ar/³⁶Ar ratios of mantle-derived igneous rocks have increased steadily over the past 800 Myr. (2) The present-day ⁴⁰Ar/³⁶Ar ratios in the upper mantle and atmosphere are very similar. (3) The majority of argon at present in the atmosphere has been derived from the mantle rather than the crust. (4) Initial ⁴⁰Ar/³⁶Ar ratios on igneous rocks are potentially more sensitive petrogenetic indicators than strontium or lead isotopes.

Calculation of argon isochron parameters from the literature suffers from several omissions in the presentation of K-Ar age data for publication and we suggest the following minimum list of items that need to be reported: (1) The measured argon ratio in air. (2) The system line blank and isotopic ratio. (3) The weight of sample fused. (4) The concentration of ³⁶Ar measured or the percentage of 'atmospheric' to 3 significant figures.

We acknowledge early discussions with Drs Pankhurst and O'Nions at the University of Oxford, and Dr John Mitchell at the University of Newcastle-upon-Tyne.

Plate tectonics, volcanism and the lithosphere in British Columbia

THE most important feature of the present tectonic situation off the west coast of Canada is the ridge-trench-fault type triple junction between the Juan de Fuca, Pacific and American lithospheric plates near the continental margin, at approximately 51°N (Fig. 1). The half spreading rate for the Juan de Fuca Ridge, based on the magnetic lineation pattern, is 2.9 cm yr⁻¹, and the calculated rate of motion along the Queen Charlotte transform fault between the American and Pacific Plates is 6 cm yr⁻¹ (ref. 1). The main part of the Juan de Fuca Ridge is probably spreading parallel to the north-east trending Blanco fracture zone which marks the southern edge of the plate at approximately 43.5°N. The vector diagram for the relative motion of the three plates during the late Cainozoic suggests

Fig. 2 The Canadian Cordillera and the adjacent north-east Pacific Ocean viewed from the north-east. a, 'arc' volcanics over the subducted part of the Juan de Fuca Plate; b, American Plate; c, lithosphere; d, Queen Charlotte Transform Fault; e, Pacific Plate; f, east-west volcanic lineaments; g, Juan de Fuca Ridge; h, Juan de Fuca Plate. Note the flexing of the American plate and the associated east-west topographic and volcanic lineaments (f) at approximately 51°N; the oblique underthrusting of the Pacific Plate along the Queen Charlotte Fault (d), and the associated north-south volcanic belt of British Columbia north of 53°N.

Fig. 1 Plate boundaries (after Atwater¹) and the volcanic (after Souther⁶) and topographic lineaments of the Canadian Cordillera. ●, Volcanic centres; double heavy lines, ridges; heavy, crossed, lines, trench; heavy line with reversed arrows, transform fault; thin close-set lines, east-west topographic lineaments.

that the Juan de Fuca Plate is being thrust obliquely below the American Plate at 2.5 cm yr⁻¹ in a direction of N 35° E (ref. 1).

Travel-time anomalies for the Seattle earthquake which occurred at a depth of 60 km, indicate the existence of a high velocity slab dipping eastwards at 50° beneath south-western Canada and the north-western United States². The magnetic anomalies of the Juan de Fuca Plate continue across the continental slope, and there is evidence of steep reverse faulting on the slope parallel to the continental margin³. Both these lines of evidence indicate recent subduction of the Juan de Fuca Plate below the American plate, as does the presence, further inland, of the late Cainozoic andesitic volcanic belt of the Cascades.

In the absence of a Benioff seismic zone, however, it is difficult to say how far the subducted Juan de Fuca Plate may extend to the east below the Cordillera. I here suggest that a number of phenomena within the Canadian part of the Cordillera, in the vicinity of the triple junction between the Juan de Fuca, Pacific and American Plates, can be explained if the influence of the subducted plate extends at least 500 km eastwards from the continental margin.

The most obvious physiographic feature of the Canadian Cordillera is that the area south of 51°N, the latitude of the triple junction, is approximately 500 m higher than that to the north. Geologically, there is more granitic 'basement' exposed to the south than there is to the north⁴, and in the eastern metamorphic belt of the Cordillera, the highest grades of metamorphism are again south of 51°N and decrease rapidly northwards⁵. These features all suggest that there has been a greater degree of uplift and erosion south of 51°N.

More than 90% of the approximately 150 Pleistocene and Recent volcanic centres which have been identified in the Canadian Cordillera⁶, fall within the two north-south belts and one east-west belt (Fig. 1). The volcanic centres are generally short-lived cinder cones with alkali olivine basalt flows, but at least 20 are composite volcanoes with flows ranging from picrite basalt, through alkaline andesite and dacite, to rhyolite. The north-south line of volcanic centres in southern British Columbia could be the northern continuation of the Cascade andesitic volcanic centres, and part of a volcanic arc over the subducted portion of the Juan de Fuca Plate. The greater arc-trench distance in Canada may indicate that the plate dips eastwards at a shallower angle north of 49°N. The east-west volcanic belt is at approximately the same latitude as the triple

junction on the continental margin, and the belt may be related to an upward bending of the American Plate over the northern edge of the Juan de Fuca Plate⁷, with magma generated by partial melting in the zone of tension at the base of the lithosphere (Fig. 2). South of the east-west volcanic belt, the reverse bend causes tension in the upper part of the lithosphere. The consequent east-west fracturing has been emphasised by subsequent erosion, producing the prominent east-west lineations in the Coast Mountains (Fig. 2). Preliminary interpretation of gravity data over Queen Charlotte Sound suggests that the east-west topography of the Coast Mountains continues below the sedimentary cover of the continental shelf north of Vancouver Island. The oldest identified sediments overlying this topography are late Miocene⁸, which indicates that the triple junction to the west has remained at approximately the same latitude for the last 15 Myr.

The model in Fig. 2 also relates the north-south volcanic belt of north-western British Columbia to a lithospheric flexure, in this case caused by the oblique convergence of the Pacific and American Plates. Data from this northern region are scarce, but one fault-plane solution for the 1949 Queen Charlotte earthquake (54.1°N, 132.6°W) requires right lateral slip, with some underthrusting of the Pacific Plate below the American Plate⁹. Seismic profiling across the southern end of the Queen Charlotte Fault (52°N) has shown a raised block of oceanic crust at the foot of the continental slope¹⁰. It is possible that this block was raised by reverse faulting similar to that found along the continental slope further south, where the faulting is believed to be related to subduction of the Juan de Fuca Plate below the American Plate³. In the St Elias mountains near the junction of the borders of Alaska, Yukon and British Columbia, there are marine Pliocene sediments which have been raised at least 6,400 m since deposition⁶. Thus, there is evidence that the Pacific Plate has been thrust obliquely under the American Plate, with the western margin of the latter raised to the north of the triple junction (Fig. 2). Tension at the base of the bent plate could have caused the observed volcanic lineament. With this interpretation the Queen Charlotte Fault cannot be regarded as a true transform fault (compare with Fig. 1) because of the element of convergence between the Pacific and American Plates.

The half wavelength of the flexure in the American Plate between the east-west volcanic belt and the parallel zone of topographic lineaments to the south, is 200 km and, assuming that the density between the lithosphere and the supporting asthenosphere is 3.3 g cm^{-3} and $g = 980 \text{ cm s}^{-2}$ the apparent flexural rigidity of the plate¹¹ will be $1.3 \times 10^{22} \text{ Nm}$. The thickness of the lithosphere¹¹, using a Poisson's Ratio of 0.25 and a Young's Modulus of $7 \times 10^{10} \text{ N m}^{-2}$ will then be 28 km. A similar value for the thickness of the lithosphere has been obtained from a study of the deformation of glacial lake shorelines by Fulton and Walcott¹² who estimated the lithosphere in the Cordillera south of 51°N to be 20–50 km thick. Even within these wide limits, the lithosphere is considerably thinner than the 110 km found below stable areas of the crust.

The concept of an abnormally thin lithosphere below the southern part of the Canadian Cordillera supports earlier ideas. For instance, Caner¹³ invoked a layer of possible partial melting in the lower crust to account for anomalous variations in the Earth's magnetic field in the south-eastern part of the Cordillera. Wickens¹⁴ has shown that the low velocity layer equivalent to the asthenosphere, approaches the base of the crust below the southern part of the Cordillera. The thickness of the lithosphere is approximately equal to the depth of the M discontinuity derived from refraction seismic data, suggesting that the upper surface of the asthenosphere approaches the base of the crust in this part of the Cordillera. The P_n velocity over the subducted part of the Juan de Fuca Plate is low (approximately 7.8 km s^{-1} , Berry, personal communication, 1973) and I have concluded⁷ that the density of the upper mantle below the central part of the Cordillera has also to be lower than normal in order to reconcile the gravity and refrac-

tion seismic results. As may be expected from the model in Fig. 2, P_n for the central part of the Cordillera increases to a more normal value of 8.1 km s^{-1} north of the latitude of the triple junction and the area overlying the Juan de Fuca plate.

Isotopic analysis of the deep structure in the Tyrrhenian Sea

THE monotonic distribution of temperature and salinity with depth, observed in most oceans of the world is replaced, in certain areas, by a peculiar 'staircase' structure in which sheets of water of constant temperature and salinity are separated by comparatively thin layers, across which there is a sharp gradient. Although its origin is speculative, the structure is often associated with the intrusion of warm saline water into a water mass that is colder and fresher. The structure is present in the eastern Atlantic, west of Gibraltar, below the characteristic Mediterranean outflow^{1,2}, and in the Tyrrhenian Sea below the inflow of the Levantine Intermediate Water through the Strait of Sicily^{3,4}.

We have attempted to distinguish the layers in the Tyrrhenian Sea by isotopic analysis of water samples collected from the different layers.

The Mediterranean is divided into two main basins by the Strait of Sicily. The eastern part is referred to as a 'concentration basin': the amount of water lost by evaporation exceeds the amount gained by precipitation and river discharge. In order to maintain the water and salt balance, two opposite flows connect the eastern and western basins through the Strait of Sicily. The upper flow, towards the east, carries in more 'Atlantic' water of lower salinity than the opposite flow at the bottom^{5,6}.

The deeper flow, the Levantine Intermediate water, is characterised by a salinity of about 38.7‰ and a temperature of about 14°C, and, after passing the sill, descends to a level of stability at a depth of about 600 m in the Tyrrhenian Sea. As it extends northwards and eastwards, it can be identified by the observed maxima in temperature and salinity profiles. It is the water mass below this maximum which, at some locations, exhibits the 'staircase' structure, although at other locations the more normal monotonic decrease to the bottom is observed.

In May 1972, samples were taken from 24 stations in the Tyrrhenian Sea, using a salinity-temperature-density (STD) probe. In addition, Nansen casts immediately followed the STD casts in five of the locations. At the station which exhibited the most pronounced structure, samples were taken at six depths below the salinity maximum (Fig. 1).

Fig. 1 Salinity, temperature and isotopic profiles at hydrographic station 19B1 in the low Tyrrhenian sea (39° 59.0'N, 12° 42.5'E). a, b, results relative to SMOW.

The isotopic analysis concerned the concentration of the stable ^{18}O content of water and of the dissolved sulphate, and the tritium concentration in superficial and deep seawater samples.

The procedure used in the preparation of samples for measuring the $^{18}\text{O}/^{16}\text{O}$ ratios in sulphate ions has been described⁷. The oxygen isotope analyses were carried out using the graphite-reduction technique⁸.

Oxygen isotope ratios are given in δ notation:

$$\delta^{18}\text{O} = \left\{ \left[\frac{(^{18}\text{O}/^{16}\text{O})_{\text{sample}}}{(^{18}\text{O}/^{16}\text{O})_{\text{standard}}} \right] - 1 \right\} \times 10^3$$

The results are reported relative to Standard Mean Ocean Water (SMOW)⁹. Isotopic analyses of the CO_2 were made using an ATLAS M86 mass spectrometer. The expected error of the $\delta^{18}\text{O}(\text{SO}_4^{2-})$ measurements was estimated at $\pm 0.07\text{‰}$.

Water oxygen isotopic samples were prepared using the isotopic equilibration technique¹⁰. The expected error of the $\delta^{18}\text{O}(\text{H}_2\text{O})$ measurements is $\pm 0.1\text{‰}$.

Tritium is formed in the atmosphere by, essentially, three mechanisms: the interaction of the nucleonic components of the cosmic radiation with the constituents of the atmosphere; direct origin from the Sun; and thermonuclear weapon tests. Most of the atmospheric tritium will form water and enters the oceans as tritiated water by molecular exchange across the air-water interface.

The concentrations are reported as TU (tritium unit); that is, the number of tritium atoms relative to 10^{18} hydrogen atoms¹¹. The accuracy of the tritium concentration measurement is approximately ± 1 TU.

Table 1 presents the results of the isotope analysis together with the observed temperature and salinity of the samples. All

* Results relative to SMOW.

† (B), Bucket samples from the surface.

STD casts were made with a Nansen bottle attached above the probe for calibration purposes. Corrected depths were calculated using unprotected thermometers.

The $\delta^{18}\text{O}(\text{SO}_4^{2-})$ values range from 9.31‰ to 9.65‰, with an average value of 9.44‰. This agrees well with a previously reported value of 9.47 ± 0.19 ‰ from the Tyrrhenian Sea¹². In the region of pronounced step structure (Station 19B1) the $\delta^{18}\text{O}(\text{SO}_4^{2-})$ values lie between 9.57‰ at 547 m depth and 9.34‰ at 900–1,000 m.

The $\delta^{18}\text{O}(\text{H}_2\text{O})$ analysis, made only at station 19B1, showed an increase from a value of about 0.7‰ in the surface waters to a value of about 1.3‰ in water below 600 m.

A net decrease of tritium concentration with depth can be seen at all stations. The tritium concentration in the thermocline area (Station 19B1) is very uniform (about 12 TU) and considerably higher than in subjacent waters. In the intermediate Levantine water (about 600 m) the tritium concentration is 6 TU.

In the region of the stepped structure the tritium content decreases with depth (2.8 ± 0.6 TU), but the disparity is a little lower than the expected error. The deepest water sample is 'dead'.

It must be admitted that the results of this first attempt to detect significant differences in the isotope concentration of the separate layers are inconclusive. There is no doubt that both in the layered structure and at adjacent stations where the layering is not marked, the tritium concentration decreases with depth, and the tritium contents in the stepped portion of the TDS profile at station 19B1 may be taken as an indication that the observed steps concern a water mass showing a uniform apparent age, intermediate to those of the overlying Levantine and underlying deeper waters. If, as is probable, the stepped water mass results from mixing between the Levantine Intermediate water and the deep, 'dead', water, then at different times correspondingly different degrees of mixing and, consequently, different tritium concentrations will occur. Thus, because they have the same tritium contents, the observed layers may be formed at the same time or at very close times. There is also some indication that the tritium concentration of the Levantine Intermediate water (300–600 m) decreases to the north, though again, the differences are roughly comparable to the accuracy of the measurements.

Ophiolites and oceanic crust

OPHIOLITES consist of a pseudostratiform sequence, of harzburgite, tectonite, ultramafic and mafic cumulates sometimes including gabbro and quartz diorite (plagiogranite) intrusions, dolerite dyke swarms, pillow lava¹, and deep-sea sediments^{2–4}. This assemblage occurs in all Phanerozoic mountain systems and is interpreted as fossil oceanic crust and uppermost mantle^{5–10}. Outstanding problems include differences between the chemical properties of ophiolites and rocks thought to represent present-day oceanic crust^{11,12}, the lack in some complexes of recognised dyke swarms or cumulates, and the relative thinness of ophiolite mafic rocks compared with standard oceanic crustal sections^{5,8,13}.

We here attempt to resolve some of these difficulties by comparing data on oceanic crustal structure, with data on selected, relatively complete, ophiolite complexes. We also discuss possible relationships between age, spreading rate, and crustal structure, and suggest a more precise correlation between oceanic crustal and ophiolitic layers.

Table 1 presents data on both the internal structure of ophiolite complexes used in this comparison, and our inferred thicknesses of oceanic layers 2 and 3 (see refs 13 and 14).

Several workers have discussed the variation of oceanic crustal structure with age and rate of spreading^{15–17}. Sutton *et al.*¹⁸, reported a series of combined wide-angle reflection-refraction measurements from the Pacific Ocean, which present a somewhat different structural picture from the normal oceanic model. In particular they found abundant evidence for a basal layer of $V_p = 7.1\text{--}7.6 \text{ km s}^{-1}$ between the main oceanic layer (layer 3) and the mantle. They suggested that this layer is widespread, but seldom recognised. We here compare their results with the ocean crustal ages¹⁹ and spreading rates²⁰.

The thicknesses reported by Sutton *et al.*¹⁸ show little relationship to age of crust (Fig. 1). This contrasts with observed increases in the thickness of layer 3 (ref. 17) but it may be because of inadequate data.

Figure 2 shows that the thicknesses of the oceanic and the basal layer, respectively decrease and increase as the spreading rate increases. Comparison of seismic velocity (V_p) with spreading rate (Fig. 3) reveals little change in the oceanic layer but an apparent decrease with increasing rate in the basal layer.

Fig. 1 Relationship between the thicknesses of the oceanic (a, $V_p = 6.2\text{--}7.0 \text{ km s}^{-1}$) and basal (b, $V_p = 7.1\text{--}7.8 \text{ km s}^{-1}$) layers¹⁸ and the age of the crust.

Table 1 Age, thickness, and structure of selected ophiolite complexes

Complex	Thickness (km)				Oceanic correlation		
	Transition	Gabbro	Diabase	Lava	Layer 3	Layer 2	Total
Vourinos ⁴ (V)	1	1.6	~0.5	~0.5	1.6	1	2.6
Troodos ^{13,26} (T)	0.5	0.5	2.3	0.9	0.5	3.2	3.7
Kizil Dag ²⁷ (KD)	2.0	2		0.4	0-2	0.4-2.4	2.4
Semail ^{6,7} (S)		3	2	1	3	3	6
Othris ²⁸ (O)		0.25		0.6	0-0.25	0.6-0.85	0.85
Pindos ^{25,27} (Pi)		~1	~1	0.3	1	1.3	2.3
Papua ³⁰ (Pa)	0.5	4		4-6	4	5±1	9
Elba ^{31,32} (E)		0.1	1.1		0.1	1.1	1.2
Betts Cove ³³ (BC)		0.2	1	1	0.2	2	2.2
Canyon Mountain ⁹ (CM)		3.1		0.4	3.1	0.4	3.5
Bay of Islands ⁸ (BI)	0.8	2.6	0.6	1.2	2.6	1.8	4.4

The thicknesses of the units are only approximate. They are either taken from the references indicated, or measured from published cross sections.

The sections of Sutton *et al.*¹⁸ closely resemble those of the selected ophiolite complexes (Fig. 4). The range of thickness of the oceanic layer (approximately 1-5 km), is surprisingly similar to the inferred range of thickness of layer 3 (gabbro) in ophiolites (0.25-4 km).

Furthermore, the presence of a basal layer intermediate in velocity between the oceanic layer and the mantle, also has a geological counterpart in ophiolite complexes, that is, the mixed mafic-ultramafic or 'transition' zones of many

there is slow cooling, with a lot of diffusion and secondary enlargement, resulting in a thinner, higher velocity, basal layer, and a thicker, lower velocity, oceanic layer. Data from fast spreading ridges suggest that cooling is faster, with less diffusion, and a high degree of space filling, giving rise to a thicker, lower velocity, basal layer, and a thinner, higher velocity, oceanic layer (see Figs 3 and 4). It must be emphasised, however, that the seismic data are sparse and highly variable and that the mixed mafic-ultramafic zones of many ophiolites are complicated by pyroxenite and gabbro dykes, and above all, are commonly partially serpentinised. It is possibly these geological features which give rise to the scatter in Figs 1-3.

Some olivine cumulates in the Pindos complex²⁵ contain as much as 25% plagioclase and 2% pyroxene, whereas olivine cumulates in the Vourinos complex²¹ are essentially monomineralic (dunites). These relationships imply that primary cumulus processes are first order determinants of oceanic and basal layer thicknesses and velocities. Pindos may have formed from a faster spreading ridge than Vourinos.

Fig. 2 Relationship between the thicknesses of the oceanic (a) and basal (b) layers¹⁸ and the spreading rate.

ophiolites. These zones are composed principally of layered cumulates, which in at least one case (Vourinos) are arranged in cyclic units²¹. The interstices between cumulus crystals (for example, olivine) may be filled by material of the same composition as the crystal itself²² (thereby forming, for example, a dunite); or they may be filled by other minerals (for example, plagioclase and pyroxene)²² thereby forming, for example, a plagioclase hertzolite or wehrlite. As the postcumulus material comprises as much as 50% of a cumulate, fairly large differences of seismic velocity can be expected, depending on the relative amounts of 'secondary enlargement space filling' material.

These differences are of fundamental importance in any consideration of magmatic processes at a ridge, because 'secondary enlargement' apparently is controlled by the rate of accumulation of cumulus crystals in layered cumulus complexes²³. When the rate of accumulation is slow, diffusion operates to produce enlargement. When the rate is rapid, the original magma effectively is trapped and 'space filling material' is formed. This relationship is evident in the Stillwater complex where there is an inverse relationship between the thickness of section of olivine cumulate and the amount of enlargement²⁴.

Thus, the data suggest that in slow spreading ridges,

Fig. 3 Relationship between velocity (V_p) in basal (a) and oceanic (b) layers and spreading rate.

Completely unserpentinised ultramafics are rare in ophiolite complexes, but occur in a few, such as Vourinos or Papua. Possibly the serpentinised-fresh ultramafic contact in these complexes represents the seismic Moho rather than the mafic-ultramafic contact. Whether serpentinised or not, it is apparent that the basal layer-mantle interface may not correspond to the magmatic-metamorphic contact of ophiolites^{1,21}.

It is not yet possible to infer a spreading rate for a given ophiolite complex by comparing the internal structure and petrology with seismic data of oceanic crust, but some trends are emerging. It seems reasonable to assume, however, an oceanic crustal mode as follows: layer 2=pillow lava, and dolerite, or zeole-greenschist

Fig. 4 Upper row, crustal sections of the Pacific basin¹⁸. Numbers over sections are sites of Sutton *et al.*¹⁸. Numbers within sections are seismic velocities (km s⁻¹). Lower row, selected ophiolite complexes. e, Extrusives, generally mafic pillow lava; d, dolerite; g, gabbro +, mixed mafic-ultramafic or 'transition' zone. Symbols for ophiolite complexes are from Table 1.

facies equivalents^{15,16}, oceanic layer (layer 3)=gabbro, and quartz diorite (plagionite) and/or amphibolite; basal layer=a mixed ultramafic cumulate zone together with partly serpentinised tectonite.

Refinement of the model awaits more data on ophiolite, oceanic crustal lithologies, and thicknesses and elastic properties, obtained either seismically or by drill sampling. The elastic properties of ocean ridge dredge samples confirm that layer 2 is basaltic and the oceanic layer (layer 3) is gabbroic, but identification of basal layer rocks is unlikely using this approach, and coherent stratigraphy is difficult to establish in dredge hauls. The ultimate aim is the calibration of ophiolite spreading rates, and thus those of now vanished Phanerozoic oceans.

Optical absorption phenomena at electrode surfaces

THERE has been a considerable expansion recently, in the application of optical techniques, such as internal reflection and specular reflection spectroscopy, ellipsometry, interferometry, holography and optical microscopy, to the study of adsorption phenomena in electrochemical reactions¹⁻³.

In general, these methods have been used to study the optical properties of the electrode material and of thin films adsorbed on to their surfaces. Internal reflection spectroscopy and specular reflection spectroscopy have both been used to monitor the surface concentration of an electroactive species⁴⁻⁶.

We describe here some preliminary observations of the optical absorption phenomena which occur above a platinum cathode surface when dilute aqueous solutions of metal cations containing a preponderant concentration of an indifferent electrolyte, such as an alkali metal halide, are electrolysed at low current densities and controlled potentials in a silica cuvette.

Well defined transient absorption spectra are obtained both 'on' the cathode surface and as much as 10^6 – 10^7 Å into the solution phase. The wavelengths of the absorption maxima of the transient absorption bands bear a close relationship to the shorter wavelength absorption lines of the same atomic species in a gas phase. Furthermore, the peak intensities of these transient signals are proportional, in each case, to the concentration of the free electroactive cations in solution. No corresponding signals are observed at the anode or in the absence of the electroactive species, or at potentials below that required to discharge the particular cation. The signals are most intense at grazing incidence on the cathode, but they are also found in the solution phase when the cathode is below the analysing light beam.

Fig. 1 Variation of absorbance (207 nm) with voltage. Upper curve, 5 p.p.m. Zn^{2+} in 0.03 M K_2SO_4 ; lower curve, 0.03 M K_2SO_4 only.

These observations suggest the transient existence of hydrated free atoms in the solution, close to the cathode surface. It is probable that these are formed by a process of electron tunneling from the cathode with the formation of hydrated electrons which subsequently reduce the hydrated, or otherwise liganded, cations.

These experiments suggest to us the basis of a potentially useful analytical trace technique of hydrated (solvated) atomic absorption spectroscopy (T. S. West, Fourth International Conference on Atomic Spectroscopy, Toronto, unpublished). The technique may also prove useful for the examination of surface mechanisms in electrodeposition and electrochemistry in general.

A simple ultraviolet/visible spectrophotometer was built from a hydrogen lamp and power supply, a tungsten filament lamp, a monochromator, and a photomultiplier tube with a Branden-

Fig. 2 Variation of absorbance with wavelength; 10 p.p.m. Zn^{2+} in 0.03 M K_2SO_4 at -1.4 V.

burg type 475R e.h.t. power supply. The output was monitored by a chart recorder. A 20-mm silica cell was used, with two platinum plate electrodes inserted. A potentiostatic waveform source was used as a signal generator. The alignment was such that a narrow collimated beam of light passed over the surface of the cathode, with the anode kept well clear of the light path. The cathode could be racked upwards or downwards in the light beam.

Each element was studied by using the highest possible potential difference in order to find a wavelength at which a maximum transient increase in absorption was obtained. At that wavelength, the optimum electrode pretreatment conditions and potential difference were found, and, using these, the variations of absorbance with wavelength and with concentration of metal cation were obtained.

The stock solutions were diluted to give solutions of (typically) 10 parts per million (p.p.m.) in 0.03 M K_2SO_4 or 0.1 M KCl . A 5 cm³ aliquot was placed in the cell and de-aerated with oxygen-free nitrogen. The gain of the system was adjusted so that zero absorbance was registered, and a potential step (square wave) was imposed on the electrodes so that the electrode in the light path became the cathode. After the change in absorbance had been recorded, the cell was emptied (by suction) and the working electrode was washed with dilute base electrolyte while a high positive potential (up to 5.0 V) was applied—that is, it was cleaned by anodic stripping. If necessary, any surface oxide was reduced by reversing the polarity of the system.

Using this technique we studied the following metal ions: Cu^{2+} , Cd^{2+} , Fe^{2+} , Fe^{3+} , Pb^{2+} , Zn^{2+} , Co^{2+} and Ni^{2+} . On applying a potential difference between the electrodes a transient increase in absorbance was observed. This change in absorbance

has been interpreted as absorption of light by reduced species generated on or near the cathode surface.

A variation of absorbance with voltage was observed, in most cases, after a simple step function had been applied, that is, the potential difference was stepped from 0.0 V to the preset required value. Pulsed square wave functions were also used (both between zero and the required voltage and between positive and negative values) but, in general, these did not increase the magnitude of the absorbance obtained. The magnitude of the potential difference is limited by cathodic evolution of hydrogen (it was limited to about -2.2 V in 0.03 M K_2SO_4). At the absorption maximum, plots of absorbance against potential difference were obtained. These have the appearance of d.c. polarograms; as the potential difference is increased, the absorbance increases until a plateau region occurs. This persists as the applied potential difference is progressively increased until the background electrolyte begins to be reduced, or hydrogen is evolved, at which point a rapid increase in absorbance, resulting from scattering, is observed. Zinc typically has a plateau region of -1.1 to -2.0 V (Fig. 1).

With an oxidised cathode an increased signal was obtained at lower potential differences. At -2.0 V the nature of the pre-treatment had no effect on the magnitude of the absorbance signals observed for any of the cations.

With the background electrolyte alone, no absorbance was observed at wavelengths greater than 210 nm. Below this, a band with a maximum absorbance of about 0.25 (half bandwidth 10 nm) was observed at 197 nm.

Plots of absorbance against wavelength were made at the optimum observed conditions. Generally, these are, not unexpectedly, much broader than gas phase absorption lines and have a single maximum occurring in the ultraviolet. For example, zinc has a maximum at 207 nm and a half bandwidth of 16 nm (Fig. 2). The spectra for the other metals so far examined are broader.

Absorbance against concentration was plotted at the absorption maximum for each metal. Generally, the plots were linear, over a variety of concentration ranges. The zinc calibration was linear between 1 and 12 p.p.m.

The absorption typically reached its maximum value after approximately 30 s and then decayed to the initial value over a period of up to 2 min if the applied potential was maintained. The decay was more rapid if the potential difference reverted to zero at, or just after, the maximum absorbance had been reached.

The maximum absorbance was only maintained if an oscillating voltage function (both positive and negative going) was used at a frequency greater than 0.1 Hz.

Although some metals give rise to more intensely absorbing species, there is a concentration range for each metal so far studied, over which the absorbance is a linear function of concentration. This, together with the possibility of achieving selectivity with a suitable choice of wavelength and voltage, or with selective complexing and masking (as in the preconcentration step in voltammetric stripping analysis), points the way to analytical applications.

We thank the Science Research Council for the award of a research studentship to J. F. T.

BIOLOGICAL SCIENCES

Comparison of predicted and experimentally determined secondary structure of adenyl kinase

It is generally accepted that the action of a protein cannot be understood until its three-dimensional structure is known. At present, X-ray analysis of protein crystals is the only method of obtaining such structural information. It is to be feared, however, that many important proteins will never give suitable crystals so that one is obliged to consider other approaches to structure elucidation. Renaturation experiments indicated¹⁻⁴ that the three-dimensional structure of many if not all proteins is a unique function of their amino acid sequence. Therefore, in principle one should be able to determine these structures by using only the information contained in the sequence. A first step in this direction is the prediction of secondary structures (α helices, β pleated sheets, β bends) in globular proteins from amino acid sequences. Several prediction schemes have been devised to this end⁵⁻²³. It is the aim of this paper to demonstrate directly the current standing of such methods.

The enzyme adenyl kinase (adenylate kinase, EC 2.7.4.3, molecular weight 21,600) (ref. 24) was taken as a test object. Its amino acid sequence²⁵ was distributed to several groups known to work on prediction schemes. None of these groups knew the three-dimensional structure²⁶ of the protein when giving their prediction; and they were not informed about structural relationships²⁷ between adenyl kinase and other proteins. Therefore, none of the predictions can be biased by previous structural information.

The predicted and the experimentally determined secondary structures in adenyl kinase are compiled in Fig. 1. The experimental data are derived from a 3 Å electron density map. Although such a map is not detailed enough to show hydrogen bonds directly, most of the secondary structures are clearly visible. There are considerable differences between the prediction methods that have been applied. Detailed descriptions of the individual schemes can be found in the references given in the legend of Fig. 1. As shown in the lowest part of Fig. 1 the α helix predictions correspond very well with the experimental data. Two groups found nine, two groups found eight, and one group found seven out of the 10 helices. Only one of these five groups predicted a wrong piece of chain as being helical. The results in Fig. 1 indicate, however, that it is still difficult to find the correct starting and termination point of a helix.

A conventional way of estimating the success of a particular prediction scheme is to compare the prediction with the experiment in every single residue²⁸. Therefore, scores have been made which are listed on the right side of Fig. 1. One group gave an inverse prediction, that is, helix breakers instead of helical residues. To avoid confusion this kind of prediction has not been scored. A 'joint prediction' of α helices was produced by adding predictions A to J at each residue and displaying the result as a histogram. This histogram is in good agreement with the experimental data except for the C-terminal region.

Four groups predicted those residues that are involved in pleated sheet structures and one group assigned sheet-breaking residues. Again, scores have been taken and a joint prediction histogram has been produced. The results show that the three central strands (around residues 12, 91, and 116) of the five-

Prices are subject to change without notice

The text of the 1955 German edition, *Temperatur und Leben*, by Precht, Christophersen and Hensel has been completely revised and substantially enlarged for the English edition.

The great difference between this and the earlier work in German is that in 1955 there had been no book on the subject for 20 years, so that the material was virtually novel. Since then a number of books and review articles have appeared, but none of these gives a complete survey of the whole subject. When setting out to cover such a large canvas, it is essential to maintain the balance between the various parts of the picture; thus, the physiological aspects of temperature adaptation are always well to the fore. It is also necessary to ensure that all are viewed from approximately similar standpoints: for instance, the decision was taken always to mention species that diverge from the norm.

The book is addressed primarily to biologists, whether microbiologists, botanists or zoologists, but could appeal to physicians and others with an interest in thermoregulation and temperature adaptation in warm-blooded animals, man among them.

PORTABLE WATER BATH WB/100

A lightweight portable Water Bath weighing only 4lb. (1.8Kg) when fully loaded with rack and tubes. It is absolutely ideal for carrying out small scale tests and one off jobs. The versatility of this portable unit has been proved in many areas, such as:— Fume Chamber or Protective Cabinet, Tube agglutinations, Haemolysin tests, Hydrolysis, "Thrombotest", Vidal test, Routine Haematology Water Bath and so on.

WHICH WATER BATH?

WATER BATH GWB/200A

For blood coagulation techniques, prothrombin and progressive coagulation.

A specially designed glass-panelled water bath for the observation of materials under test whilst keeping them at the required temperature: e.g. 37° C for Prothrombin activity determination. For such purposes the bath can be coupled with an adjustable viewing lamp GWB/L9. Extremely useful in teaching students and in certain post-graduate classes.

GWB/L9

This lamp has the feature of a rotatable dual-purpose reflector, one side natural anodised aluminium and the other matt black. This allows a very wide range of incident light intensity.

For full information on Water Baths, please write or telephone:

LUCKHAM LIMITED

A new UV Visible & Spectrophotometer

ACTA M VII UV/Vis. to NIR Spectrophotometer offers the sophisticated researcher the latest analytical and operational flexibility in the UV/Visible Near IR region of 190-3000nm. The high performance features of this instrument provide the user with the ultimate in wavelength accuracy, resolution, and readability. No other instrument available today features such outstanding capability.

☐ DOUBLE MONOCHROMATOR-ALL GRATING

A dual grating double monochromator provides unparalleled resolution throughout the wavelength region together with exceptionally low stray light. The resolution is *better* than 0.05 nm in the Visible and UV and *better* than 0.3 nm in the Near IR. The stray light is *better* than 0.0001% in the region 240-500 nm and better than 0.01% at 2740 nm.

☐ HIGH ENERGY + LOW STRAY LIGHT

The High energy and low stray light give a large photometric range and high sensitivity with digital readout to the fourth decimal place in Absorbance in the range 0-1.2A and digital readout to three decimal places in the range 0-3A. Ten Absorbance ranges are provided for the integral potentiometric recorder from 0.01A full scale to 3A full scale.

☐ FIRST DERIVATIVE SCANNING

First derivative scanning is provided with 5 ranges from 0.01-0.2 equivalent absorbance units.

☐ FLEXIBILITY

The flexibility of the system is enhanced by providing 8 wavelength scanning speeds and 7 chart speeds all selected by push button (stepper motors are used both in wavelength and chart drive). Photometric readout can be in Absorbance units, % T., or in Concentration units with 5 possible values of period control between 0.5 and 8 seconds.

☐ LARGE SAMPLE COMPARTMENT

The large sample compartment with 1 inch beam separation and centre focus is particularly accessible. The wide range of accessories available fit on fixed mount rails for reproducible sample positioning.

☐ REPEAT SCANNING

Repeat scanning, either serial or overlay, automatic source change and calibrated zero suppression are standard operating features. To ensure correct operation, a dynode voltage indicator is fitted together with an invalid control light which indicates improper wavelength scan, and chart speed selection.

These outstanding features of the ACTA M VII make it a top-of-the-line instrument for performing sophisticated and dedicated analytical work in a variety of industrial and bio-medical

Near IR Grating from Beckman

applications. This work includes analysis of chemicals, pharmaceuticals, water and air pollution, water and gas in hydrocarbons, hydrogen bonding, and many other industrial and quality control applications. In biomedical research the ACTA M VII is used for high absorbance analyses, protein and amino acid structures and other high-grade, analytical work.

For less demanding applications the dual grating single monochromator ACTA M IV has the operating features of the ACTA M VII being limited only by the capabilities of the single monochromator.

Both ACTA M VII and ACTA M IV are computer compatible and are supported by a wide range of accessories.

For further information please write, telephone or Telex the address below.

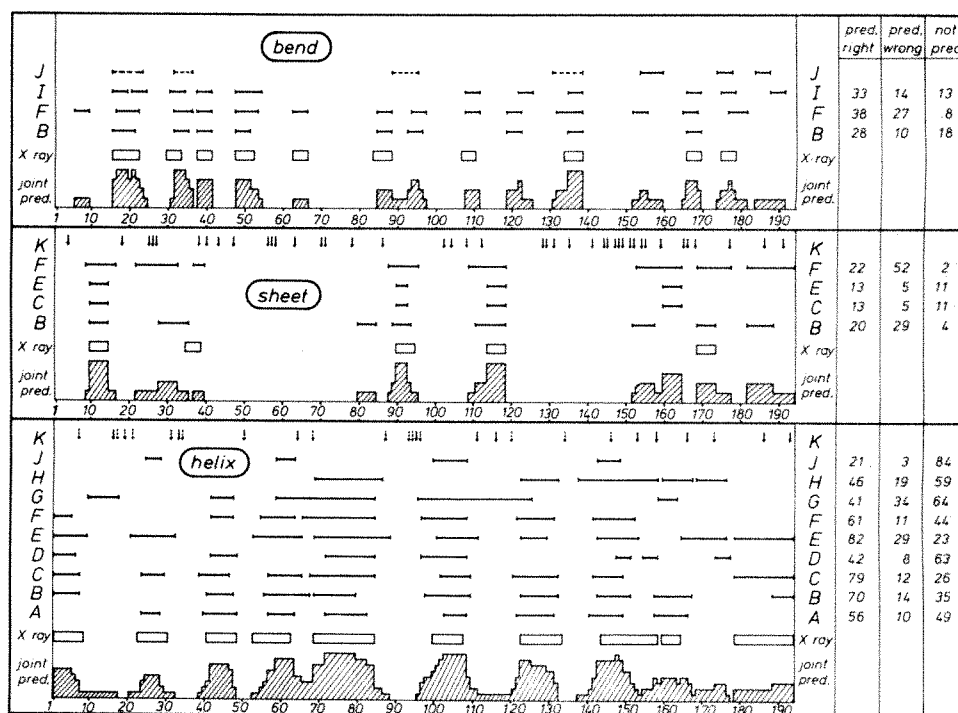

Fig. 1 Comparison of predicted and experimentally determined α helices, strands of β -pleated sheets, and bends in adenylyl kinase. The experimental data (X-ray) have been derived from a 3 Å electron density map. At this resolution the exact geometry of bends cannot be evaluated with certainty. Therefore, the experimentally determined bends in Fig. 1 are defined as changes of more than 120° in the overall direction of the polypeptide chain and without reference to any hydrogen bonding scheme. None of the predictions is biased by previous structural information about the enzyme. The predictions A to K have been supplied by A, Barry and Friedman; B, Chou and Fasman^{21,22}; C, Finkelstein and Pitsyn^{10,11}; D, Levitt and Robson^{14,32}; E, Lim²³; F, Nagano²⁰; G, Burgess and Scheraga⁸; H, Burgess and Scheraga⁸; I, Burgess and Scheraga¹³; J, Burgess and Scheraga¹⁹; K, Kabat and Wu¹⁸. They are based upon prediction schemes that have been described in the corresponding references. (The method applied by Barry and Friedman has not been published yet. It uses an analysis of the distribution of amino acids occurring at both ends of helices to define potential starting and termination points of helices in a sequence. In this method the residues three before and three after, as well as the residue defined as the beginning (or end) of an helix, are considered to be structurally significant. The predictions are based on data for 90 helices from 23 distinct three-dimensional protein structures.) Although predictions are usually made as probability profiles, all groups converted their profiles beforehand to yes or no decisions for each residue by comparing the probabilities with a given threshold value. Thus, every prediction depends on the threshold value applied³². This procedure simplified the comparison appreciably. But concomitantly, it reduced the amount of information contained in any of the predictions. Kabat and Wu predicted helix and sheet breaking residues, which are indicated by vertical arrows. Dashed arrows point to residues that are helix breaking but with a lower probability. Dashed lines in the bend prediction J indicate 'multiple bend regions'. A bend is predicted to be anywhere within such a region. Three joint prediction histograms have been produced by adding predictions A to J for helix, predictions B, C, E, and F for sheet and predictions B, F, I, and J for bends, respectively. Scores of correctly and incorrectly predicted residues as well as residues not predicted are listed on the right side of the figure.

stranded parallel pleated sheet in adenylyl kinase have been predicted correctly by all groups. This is not true, however, for the two strands at the edges of this sheet. Scores and histograms indicate that the accuracy of the β -sheet prediction is lower than the accuracy of helix or bend prediction. This might be related to the fact that the sheets are predominantly formed by interactions between residues that are far apart along the polypeptide chain (= nonlocal interactions) whereas helices and bends are caused by interactions between neighbours along the chain (= local interactions). Obviously, local interactions are more easily recognised in an amino acid sequence than nonlocal interactions, because the latter require assumptions about the three-dimensional structure.

The results in the upper part of Fig. 1 as well as the corresponding scores indicate that bends of the polypeptide chain are often successfully predicted. The joint prediction histogram shows that essentially only the bend around residue 64 has been missed. The bends predicted at residues 95 and 122 turned out to be directional changes in the polypeptide chain of only 60° and 90° , which is less than the 120° required in the definition for an experimentally determined bend (see legend of Fig. 1).

As shown in Fig. 1 some of the secondary structures have been predicted consistently whereas others were less readily recognised. The α helices in the middle of the chain and the strands in the centre of the sheet and the bends near to the N terminus were predicted consistently. There is less agreement in the C-terminal region. It is conceivable that consistent predictions are obtained in chain segments where local inter-

actions dominate the formation of secondary structures and that the predictions become more inaccurate whenever non-local interactions predominate. Thus, the prediction problems in the C-terminal region would be understood if during the folding process the C-terminal end is wrapped around a pre-existing molecular core. Nonlocal interactions with this core might force the terminal chain into its final secondary structure.

Adenylyl kinase contains a structurally rather independent domain consisting of the three helices between residues 41 and 84. The consistent prediction of these helices indicates that their formation might be dominated by local interactions. Moreover, if local interactions dominate, the helices can form spontaneously so that they may be nucleation points and the domain may be a nucleus^{21,29-31} in the folding process.

In conclusion it seems fair to state that the joint prediction histograms allow the assignment of most of the helices and bends and more than half of the sheet strands. It must be remembered, however, that adenylyl kinase is a protein with abundant secondary structures and that joint prediction histograms of other proteins might be less informative. For the same reason the merit or demerit of any prediction scheme should not be judged from its success with this particular protein alone.

We thank Drs A. W. Burgess and H. A. Scheraga who supplied four of the predictions and commented on the text.

Topological comparison of adenyl kinase with other proteins

A COMBINATION of amino acid sequence analysis¹ and X-ray analysis has yielded the atomic structure of the enzyme adenyl kinase² (adenylate kinase, EC 2.7.4.3). No protein of which the structure is known is so closely related to adenyl kinase that an amino acid sequence comparison³ or an exact geometrical comparison of the structures⁴⁻⁶ can be expected to indicate a relationship. Similarities with other proteins become apparent, however, if one restricts the comparison to topologies, that is, to chain folds without reference to the exact geometry. Since chain folds are particularly well conserved during evolution⁷ such a procedure might reveal distant relationships.

The most important structural feature of adenyl kinase is its central five-stranded parallel pleated sheet²; therefore, we shall only discuss proteins containing a similar motif. Central parallel sheets with more than three strands are present in subtilisin⁸⁻¹⁰, flavodoxin^{11,12}, and various dehydrogenases¹³⁻¹⁶. The sheets of these proteins are sketched in Fig. 1 according to a proposal of Rossmann (personal communication). The drawings contain no geometrical detail. Only the sheet strands and the approximate path of the connections between these strands (through the upper and lower side of the sheet), that is, only the sheet topology, is given. In such a presentation the topology is fully described by the strand sequence in the sheet and the above-below pattern of the connections. Since there are finite, calculable numbers of possible strand sequences and possible connection patterns, the number of possible topologies (M) is also finite and calculable.

This number can be used to define a quantitative measure of relationship between two structures. Assuming, for instance, each of two proteins contains an n -stranded parallel sheet with identical topology; since such a sheet can exist in M different topologies, the probability that by chance both sheet topologies are identical is $1/M$. Or, in other words, the significance of their relationship, which one might call 'figure of topological relatedness', is $M:1$. We shall now derive such figures within the group of protein structures shown in Fig. 1.

First we have to evaluate the number of possible strand sequences in an n -stranded parallel sheet. This is equal to $n!/2$, the number of permutations of n items reduced by a factor of 2. The halving is necessary because symmetrically related strand sequences as $ABCD$ and $DCBA$ can be superimposed by rotation. Second, we take into account that the $n-1$ connections between the strands run either through the upper or the lower side of the sheet, giving rise to 2^{n-1} possible above-below connection patterns. Combining strand sequences and connection patterns we find that there are $M = 2^{n-1} \times n!/2 = 2^{n-2} \times n!$ possible topologies. For simplicity this counting scheme disregards further topological differences which arise whenever connections cross each other as, for example, connections $A-B$ and $B-C$ in subtilisin.

One can use this formula for a comparison within the dehydrogenase family, for example, for a comparison between

Table 1 'Figures of topological relatedness' between protein structures

Compared sheet topologies		No. of strands in common for both sheets	No. of connections in common for both sheets	Uncorrected figure of topological relatedness	Reduction factor	Corrected figure of topological relatedness	Figure of topological relatedness including binding region
Adenyl kinase	Subtilisin	5	3*	480 : 1	1 × 2	240 : 1	2400 : 1
Adenyl kinase	Flavodoxin	4	3	96 : 1	2 × 2	24 : 1	240 : 1
Adenyl kinase	Any dehydrogenase	4	3	96 : 1	2 × 3	16 : 1	160 : 1
Subtilisin	Flavodoxin	5	4	960 : 1	2 × 1	480 : 1	4800 : 1
Subtilisin	Any dehydrogenase	5	4	960 : 1	2 × 2	240 : 1	2400 : 1
Flavodoxin	Any dehydrogenase	5	4	960 : 1	1 × 2	480 : 1	4800 : 1
A dehydrogenase	Another dehydrogenase	6	5	11520 : 1	1 × 1	11520 : 1	115200 : 1

* Adenyl kinase and subtilisin have five strands but only three (and not four) connections in common because connections *B-C* are different. No reduction factor for this disagreement has been applied, however, since connection *B-C* has only slipped around a sheet edge.

lactate dehydrogenase¹³ and liver alcohol dehydrogenase¹⁵. Both structures contain six-stranded parallel sheets with identical topology (Fig. 1), although there exist $M=2^{6-2} \times 6! = 11,520$ possible topologies for such a sheet. Therefore, their "figure of topological relatedness" is 11,520 : 1.

The reasoning can be extended to topologies that are identical in the central strands of the sheet but that do show differences at the sheet edges. The procedure is best described by com-

paring adenyl kinase with flavodoxin. Both structures have a four-stranded sheet (*ACDE*) and three connections (*A-B=A-C*, *C-D*, *D-E*) in common. This yields an "uncorrected figure of topological relatedness" of $2^{4-2} \times 4! : 1$ or 96:1. For the comparison, however, one strand in each protein has been discarded. When selecting these strands an arbitrary choice of one out of two possibilities in each protein (left or right edge) has been made. Since such a choice reduces the significance, a reduction factor of $2 \times 2 = 4$ was applied to the "uncorrected figure of topological relatedness", yielding a "corrected figure of topological relatedness" of 24:1 (see Table 1). An analogous procedure has been followed when comparing other pairs of structures (Table 1).

The structural relationship within the dehydrogenase family is not only indicated by correspondence of sheet topologies but also by correspondence of nucleotide binding positions¹⁶. As shown in Fig. 1, the other proteins contain similar sites at similar positions relative to the sheet. Therefore, we shall include this kind of information about relationship into the proposed quantitative measure.

For sake of simplicity we do not distinguish between different kinds of sites but merely refer to them as being a "binding region". In the view given in Fig. 1, for all proteins this binding region is located in front of the carbonyl ends of the central sheet strands, that is, above the plane of the paper. In order to use the same reasoning as before, we estimate how many positions of such a binding region we would have accepted as being different. For instance, we would have been able to distinguish between left side, centre, and right side of the sheet as well as between above, in front, in the rear, and below the sheet, that is, we would have differentiated between about 10 positions.

Since all proteins show the same binding region position out of these roughly estimated 10 possibilities, there is an additional significance of their relationship of 10:1. Thus, the 'corrected figure of topological relatedness' (Table 1) may be multiplied by a factor of 10, yielding the overall 'figure of topological relatedness including binding region' between the structures (Table 1). If a closer correspondence of the binding regions could be established, there would be more than 10 distinguishable positions and therefore a larger additional factor.

The results in Table 1 show that adenyl kinase is rather closely related to subtilisin and less closely to flavodoxin and to the dehydrogenase family. This corresponds to the strand sequence reversal *BC* compared with *CB* between adenyl kinase and subtilisin on the one hand and the dehydrogenases on the other. A relationship between the dehydrogenases, flavodoxin and subtilisin is clearly indicated.

These relationships point to either divergent or convergent evolution. Convergent evolution would be expected if the resulting topology is energetically favoured or if the topology is favoured in the dynamical folding process¹⁸ of the polypeptide chain. But this does not seem very likely. In the case of divergent evolution, however, we have to postulate a common ancestor for enzymes as distant from each other as the

Fig. 1 Topologies of proteins containing a parallel sheet. *a*, Adenyl kinase²; *b*, subtilisin⁹⁻¹⁰; *c*, flavodoxin^{11,12}; *d*, NAD-binding globules (domains) of lactate dehydrogenase¹³, s-malate dehydrogenase¹⁴, liver alcohol dehydrogenase¹⁵, and D-glyceraldehyde-3-phosphate dehydrogenase¹⁶; *pt*, hydrophobic pockets, that is, presumed binding sites for adenine²; *p*, phosphate position in the catalytic centre of adenylate kinase; *cr*, hydrophobic crevice, that is, presumed binding site for aromatic or apolar side chain¹⁰; *cc*, catalytic centre; *fl*, FMN; *nic-ad*, nicotinamide and adenine moieties of the dinucleotide NAD. In the case of adenyl kinase the five heavy circles are the five strands in the sheet. (The drawing corresponds to the linear diagram given in Fig. 3 of the adenyl kinase structure description², if one views this figure from the top along the strands in the sheet, that is, along the plane of the paper, to the bottom.) The carbonyl ends of these strands point toward the viewer. The arrows indicate the direction of the polypeptide chain³, that is strands *ABCDE* in the sheet are ordered alphabetically along the course of the chain. The sheet topologies of the other proteins have been drawn correspondingly. The topologies of the NAD-binding globules of the four dehydrogenases are identical¹⁶. The same topology might be present in horse muscle phosphoglycerate kinase¹⁷. The location of substrates (*pt*, *cr*), cosubstrates (*fl*, *nic-ad*), and catalytic centres (*cc*, *p*) are all in front of the carbonyl ends of the central strands in the sheet, that is above the plane of the paper.

bacterial extracellular protease subtilisin and the mammalian intracellular adenylyl kinase.

Stimulatory capacity of human T and B lymphocytes in the mixed leukocyte culture

LYMPHOCYTES can be separated into thymus-dependent (T) and thymus-independent (B) cells on the basis of ontogeny, surface membrane differentiation markers, and function. Thus, some functions can be attributed solely to T or B cells, whereas others require T/B cell cooperation^{1,2}. When two populations of allogeneic lymphoid cells are cultured together in the mixed leukocyte culture assay (MLC), cellular interaction leads to blastic transformation and subsequent proliferation of a portion of the cultured cells. This proliferation response originates in T lymphocytes^{3–5,30,31}. But secondary T cell-mediated B cell proliferation may in some species contribute to the overall proliferative response of T and B cells^{6–9}. The question then arises: which cell type acts as stimulator in MLC? Is the stimulus to proliferate equally transferred by T and B cells, or are the antigenic determinants responsible for MLC activation represented exclusively or preferentially on the surface of only T or B lymphocytes? Studies in mice^{8–11} indicated that T and B cells possess equal stimulatory capacities. However, in other reports the stimulatory capacity in mouse MLC was almost

Fig. 1 Stimulatory capacity of unseparated T and B peripheral blood lymphocytes in human MLC. Lymphocytes (2×10^6) were stimulated with decreasing numbers of irradiated allogeneic cells. Ordinate: ratio of stimulation (^3H -TdR uptake in allogeneic cultures over ^3H -TdR uptake in corresponding autologous cultures), as calculated from the means of triplicate cultures. Abscissa: number of stimulating cells. Left bar, Unseparated lymphocytes; Centre bar, T lymphocytes; Right bar, B lymphocytes.

exclusively attributed to B lymphocytes (refs 3 and 12, and personal communication from D. H. Sachs).

We have attempted to answer this same question for human peripheral blood lymphocytes and report here that the proliferative response in human MLC is largely the result of stimulation by B cell-bound alloantigens.

Cells responding in MLC were prepared from heparinised venous blood by centrifugation over a Ficoll-Hypaque gradient¹². This preparation regularly contained more than 90% lymphocytes, the rest being monocytes and an occasional granulocyte.

Rosette formation of human T lymphocytes with unsensitised sheep erythrocytes (SRBC)¹⁴ was utilised to separate peripheral blood lymphocytes, used as stimulating cells in MLC, into rosetting (T) and nonrosetting (B) cells. To remove monocytes, which stimulate, although weakly, in MLC¹⁵, heparinised whole blood was incubated with sterile carbonyl iron powder for 60–90 min at 37° C with continuous agitation. Subsequent centrifugation over a Ficoll-Hypaque gradient yielded lymphocyte preparations containing less than 0.1% monocytes. Using a modification of the method of Wybran *et al.*¹⁶, these lymphocytes were rosetted with neuraminidase-pretreated SRBC (N-SRBC) which bind more firmly to human T lymphocytes than do untreated SRBC^{17,18}. Samples of 0.25 ml lymphocytes in Hanks balanced salt solution (HBSS) (10^7 ml^{-1}), 0.25 ml of foetal calf serum (absorbed with SRBC; Microbiological Associates) and 0.5 ml of N-SRBC (10^8 ml^{-1}) were added to plastic test tubes, centrifuged for 8 min at 200g, and further incubated at room temperature for 60 min. The gently resuspended pellets of all tubes (containing rosetted and nonrosetted lymphocytes) were pooled, and centrifuged over a Ficoll-Hypaque gradient (30 min at 400g); rosetting cells formed the pellet and nonrosetting cells remained at the interface between the layers. The pellet lymphocytes (termed T cells here) were washed twice in HBSS, and resuspended in culture medium (see below) to the concentration needed. No efforts were made to lyse or remove the N-SRBC so as to manipulate the lymphocytes as little as possible: orienting experiments showed that the capacity of lymphocytes to stimulate or respond in MLC was unaltered by addition of similar numbers of N-SRBC. The interface cells were washed, rosetted and again centrifuged over a Ficoll-Hypaque layer, to remove residual rosetting cells. The inter-

face cells thus obtained will be termed B cells here. This procedure effectively separated T and B cells: preparations of B cells contained less than 1% rosetting lymphocytes; and less than 2% of the T lymphocytes carried detectable amounts of surface immunoglobulins, as determined by direct immunofluorescence techniques¹⁷.

MLC (1 ml each) were set up in duplicate or triplicate with 400 ml Eagle's minimal essential medium (MEM) supplemented with 75 ml of decomplexed pooled human serum, 10 ml of L-glutamine (200 mM), 10 ml of a mixture of streptomycin and penicillin (5,000 U ml⁻¹ each), and 5 ml of nonessential amino acids (Flow Laboratories). To obtain one-way stimulation in MLC, stimulating allogeneic lymphocytes were irradiated (2,500 rad; 1,660 rad min⁻¹ from a caesium source) immediately before addition in various numbers to 2×10^5 responding cells. Responsiveness in these one-way MLCs was attributed to the nonirradiated cells, whereas stimulation was considered to be a function of the irradiated cell populations. Cultures were maintained in a humidified 5% CO₂-air atmosphere at 37° C for 7 d. Lymphocyte stimulation was assessed from the uptake of tritiated thymidine (³H-TdR) into DNA during the last 4 h in culture; cells were processed as described previously¹⁹.

Decreasing numbers of stimulating unseparated, T or B lymphocytes were added to 2×10^5 responding cells. Figure 1 demonstrates that B cells stimulated three times more vigorously than T lymphocytes using a ratio of responder:stimulator cells of 1:1. When compared with unseparated lymphocytes, T cells possessed significantly lower and B cells higher stimulatory capacity ($P < 0.001$). At lower responder:stimulator ratios, these differences were less pronounced.

Mixtures with different proportions of T and B cells were prepared, and used for stimulation of allogeneic lymphocytes. Figure 2 shows the proliferative response at three different concentrations of stimulating cells. Again, the stimulatory capacity of B cells was more than three times that of T cells at a responder:stimulator ratio of 1:1. Increasing percentages of T cells among stimulating cells led to decreasing stimulation. Similar, but less striking findings were obtained with lower numbers of stimulating cells. Could the stimulatory capacity of T cells be altered by formation of rosettes? Adherence of N-SRBC may expose previously masked T cell antigens for MLC stimulation; alternatively, T cell alloantigens may be removed or altered so that the T cells' stimulatory capacity is reduced or lost. The data presented here refute these objections. The stimulatory capacity of mixed T and B cells, using a T:B cell ratio of 2:1, was close to that of unseparated lymphocytes. Since there is a T:B cell ratio of approximately 2:1 in unseparated normal peripheral blood lymphocytes^{14,17}, it can be concluded that T cells possess their original MLC-stimulating capacity after rosette formation. Data in Fig. 2 further suggest that B and T cells contribute independently and additively to the stimulatory capacity of unseparated lymphocytes. To test whether T cells could suppress the stimulatory capacity of B cells, a constant number of stimulating B cells (2×10^5) and increasing numbers of stimulating T cells (0 to 2×10^5) were added to 2×10^5 responding lymphocytes. The proliferative lymphocyte response increased with increasing numbers of stimulating T cells; this observation excluded T cell suppression of the stimulatory capacity of B cells.

These results demonstrate that the major stimulus in human MLCs has to be attributed to B cell-bound alloantigens, and that human T cells possess only weak MLC-stimulatory capacity. The strength of the stimulatory capacity of the T cell preparations renders it unlikely that the few residual contaminating B cells were solely responsible for this stimulation; true T cell-bound stimulatory capacity seems to exist in man.

We propose the following hypothesis to explain the strong

Fig. 2 Stimulatory capacity of human T and B lymphocytes in MLC. Responding cells (2×10^5) were stimulated with mixtures of allogeneic T and B cells at three different concentrations. Abscissa: percentages of T and B cells in the stimulating cell mixtures. Ordinate: ³H-TdR uptake into DNA (d.p.m.); indicated are the means \pm one s.d. of triplicate cultures. Δ , 2×10^5 stimulating cells; \bullet , 5×10^4 stimulating cells; \blacksquare , 2×10^4 stimulating cells.

B cell and weak T cell stimulatory capacity in human MLC. Serologically defined (SD) alloantigens (H-2 in the mouse, HL-A in man) were originally thought to be responsible for MLC activation²⁰. From studies in intra-H2 recombinant mouse strains²¹ and in siblings with a crossing over event within the major histocompatibility complex (MHC)^{20,22,23}, however, it is generally accepted that genes closely linked to, but genetically separable from, the two SD loci code for MLC activation (MLC loci, LD loci). Since genetic differences in the Ir region are required for strong MLC stimulation between congenic mouse strains^{21,24}, Ir-linked genes have been implicated as coding for MLC-activating gene products²⁵. A B-cell-specific alloantigen, coded by Ir-linked genes²⁶, has been suggested to be responsible for the strong one-way MLC activation observed between two recombinant mouse strains^{12,27}. But at least one other MLC locus exists within the MHC of mice, coding for a weakly stimulating alloantigenic system²⁴.

Two MLC loci have also been suggested in man, one coding for a strong and the other coding for a weak MLC-stimulating alloantigenic system^{28,29}. It is tempting to speculate that, in further analogy to the findings in the mouse, the differences in the MLC-stimulatory capacity between human T and B cells are due to different expression of MHC-determined alloantigenic gene products on T and B cells: the genetic locus responsible for strong MLC stimulation may code for B-cell-specific alloantigens, whereas the gene products of the second locus, coding for weak MLC-stimulating alloantigens, may be represented on T (and B?) cells. Further studies on the stimulatory capacity of T and B cells in siblings with a recombinational event in the MHC may substantiate this hypothesis.

Successful construction of chimaeric rabbit

CHIMAERIC mice can be made by aggregation of zona-free cleavage stage embryos, and these animals have proved useful in analysing various aspects of development and differentiation. Animals of this type are particularly suited to test models which propose that genetic information is transferred between cells, for example during antibody formation. It has been reported that RNA extracted from immunised rabbits can induce cells homozygous for one immunoglobulin allotype to synthesise antibody molecules carrying a foreign allotype characteristic of the animals from which the RNA had been extracted¹⁻³. Although chimaeric mice have been used to search for gene transfer during the normal *in vivo* response to antigen, these results have not proved conclusive⁴.

The concept of gene transfer in the immune response

Table 1 The immunoglobulin allotypic markers in the parental rabbits and their offspring

		Coat Colour	Heavy chain		Light chain	
			a1	a3	b4	b5
Parental colony	1	White	+		+	
	2	Black		+	+	+
Offspring	1	White	+		+	
	2	Chimaeric	+	+	+	+

The pattern of allotypic markers seen in the offspring has been consistently observed over an 8 month period. The threshold of detection of the 5b allotypic marker was less than 1/625 of the concentration in normal serum.

originated from work in rabbits and, in addition, the distribution of the allotypic markers in different parts of the immunoglobulin molecule⁵ make the rabbit the ideal species to answer the problem.

It is unlikely that chimaeras formed by aggregation of zona-free cleavage stage embryos will be successful in the rabbit as it has been shown that zona-free blastocysts fail to implant (C. E. Adams, unpublished). Chimaeric mice can be constructed, however, by the injection of isolated inner cell mass cells or the insertion of inner cell masses into the complete blastocyst still surrounded by a zona pellucida⁶. Here we report the successful application of this method to the rabbit.

Inner cell masses were dissected from 4-d-old blastocysts obtained from black rabbits bearing the heavy chain allotype a3 and the light chain allotypes b4 and b5, and individual inner cell masses were inserted into blastocysts, also 4 d old, obtained from white rabbits carrying the heavy chain allotype a1 and the light chain allotype b4. The blastocysts were allowed to repair during a brief incubation in culture (up to 2 h) and then returned to the uterus of pseudopregnant white rabbits which carried the a1 and b4 allotypes. Pseudopregnancy was induced 4 d before the transfer of the blastocysts.

Five blastocysts were transferred to each of two rabbits. Two offspring were obtained from one of these rabbits, and none from the other. One of the offspring was an albino rabbit, but the other was a chimaera with mixed coat colour (Fig. 1).

Fig. 1 Chimaeric rabbit, 37 d old.

Allotype analysis was carried out on the serum obtained from the two rabbits and the results are shown in Table 1. The albino rabbit contained only the a1 and b4 allotypes but the chimaeric rabbit contained the a1, a3, b4 and b5 allotypes. Further chimaeric animals with this gene combination are being produced and we are at present collecting reagents to look for gene transfer in the existing chimaera. Phenotypically the chimaeric animal is female and has produced a litter of nine albino rabbits following mating with a New Zealand white buck. Ten metaphases from circulating blood have proved to be XX. We hope animals of this type will provide an unambiguous answer to the problem of gene transfer in the immune response.

We thank S. C. Barton, K. Day and B. Burgess for their help and the Medical Research Council and Ford Foundation for support. The typing antisera were a gift from Dr Kelus.

Note added in proof: A further chimaeric rabbit has been obtained since this report was submitted for publication.

Is chiasma determination sequential?

Most cytological studies of chiasma distribution in higher plants and animals are limited to qualitative statements on the pattern of chiasma distribution along bivalents. A few quantitative studies exist, however, based on detailed measurements of chiasma positions along the extended diplotene bivalents of grasshopper and locust spermatocytes¹⁻³. These studies differ in certain respects but agree in concluding that chiasma formation or at least chiasma determination (assuming that the determination of sites for exchange is separable from exchange itself⁴) occurs sequentially along bivalents. To this extent these studies largely endorse the view originally proposed by Mather^{5,6} which was inferred from the property of chiasma interference and from observations on the frequencies of crossing over in different chromosome regions of *Drosophila melanogaster*.

The cumulative frequency distributions of chiasmata along meiotic bivalents of the locust, *Schistocerca gregaria*^{1,3} and of four species of British grasshopper², demonstrate clearly that chiasmata do not occur with equal frequencies in all chromosome regions. Certain regions, notably the telomeric, distal, ends of both metacentric and telocentric bivalents form chiasmata much more frequently than expected if chiasma distribution were uniform. This distinct peak of distally located chiasmata in all the species included in the studies quoted above has been widely interpreted as evidence that chiasma determination follows a sequential pattern starting at the telomere and extending to other bivalent regions. There is also a distinct tendency, especially in *Schistocerca gregaria*^{1,3}, for bivalents which form only one chiasma (monochiasmate bivalents) to have that chiasma localised distally. This tendency has also been held to demonstrate a sequence in chiasma determination since, for example, it is reasoned that the first-formed chiasma is the

least likely to be lost when chiasma frequency is reduced. There is also an implicit suggestion, based on this observation, of nonindependence between chiasmata formed at the telomere and those formed elsewhere, such that chiasma formation in nontelomeric regions is conditional upon previous telomeric chiasma formation—which again implies a sequence.

A critical examination of these claims shows that the case for a sequential mechanism of chiasma determination is not proved. The frequency peaks of chiasmata in certain chromosome regions, notably at the telomeres, merely denote that these regions enjoy a high probability of chiasma formation and this evidence does not necessarily imply that these chiasmata are the first formed. Likewise, the strict distal localisation of chiasmata in monochiasmate bivalents need not imply a sequence originating at the telomere. Indeed, the argument that nontelomeric chiasmata are conditional upon previous telomeric chiasma formation can be shown to contain a logical fallacy. The spurious impression of dependence is caused by the almost invariable occurrence of one chiasma in the telomeric region.

Observations on the frequency distribution of chiasmata along the bivalents of grasshoppers and locusts therefore make possible, but do not require, a sequential mechanism of chiasma determination. Other models of chiasma determination, including nonsequential models, are not excluded by this evidence and are equally valid if the evidence is taken at its face value.

An inherent feature of all sequential models of chiasma control is the necessary assumption that the control of the chiasma formed first differs fundamentally from the control of subsequent chiasmata. The principal controlling factor identified in these sequential models is chiasma interference but it is evident that this can only influence the position of the second and any subsequent chiasmata, and it follows that the position of the chiasma formed first must be determined by a quite separate control, although the actual mechanism of exchange initiation may be the same for the first chiasma as for subsequent chiasmata. The chiasma properties of a recently described meiotic mutant of rye raise some doubts concerning this distinction between various categories of chiasmata. This mutant genotype was isolated among the segregants from an interspecific cross^{7,8}, and is defective in the control of chiasma distribution⁹. Wild-type rye is characterised by pronounced distal chiasma localisation, so that bivalent arms forming a single chiasma normally have that chiasma localised in a distal, telomeric, position. Additional chiasmata, when they occur, necessarily form in more interstitial locations. According to sequential models of chiasma determination, the distal chiasmata should be regarded as the first formed and as such under a separate control from other, interstitial, chiasmata whose positions should be governed by chiasma interference.

In the distributional mutant of rye, all chiasmata are distributed in an apparently uncontrolled manner. Frequent instances of interstitial and even proximal chiasmata occur even in monochiasmate bivalents⁸, indicating a breakdown of localisation and a more random distribution pattern along bivalents than is found in wild-type rye. In addition, chiasma interference seems to be greatly reduced in intensity, or even absent, in this mutant⁸ (as judged from the Poissonian nature of the between-bivalent frequency distribution of chiasmata¹⁰). These findings indicate that a single control apparently governs the positions of all chiasmata and therefore determines both chiasma interference and chiasma localisation in rye, otherwise one might expect a differential response of these two factors to a change in the controlling mechanism. An extension of this comparison to include a large collection of diverse rye genotypes⁹ indicates that this correlated response is general and widespread (Fig. 1). Furthermore, there is evidence of similar correlated effects in certain meiotic mutants of *Drosophila melanogaster* which show both increased coincidence values (that is, reduced interference) and also nonuniform reductions in crossover frequencies along chromosomes (that is, reduced localisation)¹¹.

There is considerable evidence, therefore, for a single genetic control which governs the positions of all the chiasmata formed

Fig. 1 The relationship of between-bivalent chiasma frequency variation (between-bivalent mean square) and chiasma positional distribution along bivalents (proportion of non-distal chiasmata) for a range of rye genotypes (from Jones⁹). The between-bivalent mean square can be regarded as a rough measure of the strength of chiasma interference¹⁰ and the proportion of nondistal chiasmata is a measure of the degree of chiasma localisation. These variables are clearly correlated ($r = 0.9$; $P < 0.001$) thus indicating that these diverse aspects of chiasma variation are controlled jointly.

in a bivalent, irrespective of their relative positions. The distinction between the chiasmata formed first and subsequent chiasmata, indicated by sequential models of chiasma determination, is difficult to reconcile with this conclusion. Proponents of sequential models could still argue that separate position-determining controls for the first and subsequent chiasmata have a factor in common, but as yet there is no evidence (for example, from the analysis of mutants) for the existence of unique factors associated with these hypothetical separate controls. Models based on nonsequential determination of all chiasmata are therefore at least as acceptable on present evidence and merely require that chiasma interference and other factors such as chiasma localisation be regarded as manifestations or consequences of control rather than control mechanisms in their own right.

Decreased antibody formation in mice exposed to lead

SEVERAL environmental contaminants have been demonstrated to be synergistic to infectious agents. Polychlorinated biphenyls¹, arsenicals², cobalt sulphate³ and sulphur dioxide⁴ increased the mortality of animals infected with viral agents. Lead nitrate enhanced the mortality of mice to *Salmonella typhimurium*⁵. Some of these compounds are apparently immunosuppressive as circulating antibody titres to infectious agents from animals exposed to lead, cadmium, mercury⁶, DDT (ref. 7) and polychlorinated biphenyls⁸ were significantly lower than those from the control animals. This study was undertaken to determine if the decreased circulating antibody in animals that were exposed to lead was a result of a decrease in the number of cells producing antibody.

Swiss Webster mice 28 d old were given lead orally (1,375, 137.5 or 13.75 p.p.m.) as lead acetate in deionised water for 56 d. The controls were given deionised water. There were 120 mice in each group. The diet fed to all the mice was contaminated with 1.12 p.p.m. lead⁹.

After 56 d, all the mice were inoculated intraperitoneally with 0.2 ml. of a 2% suspension of sheep red blood cells (SRBC). Ten mice in each group were killed on days 3–7 to measure primary immune response (19S or IgM antibody) and on days 8–14 for the secondary response (7S or IgG antibody) after a second inoculation of SRBC on day 7. An additional group of mice were inoculated with SRBC while they remained on 137.5 p.p.m. lead. The spleen from each mouse was immediately removed, cut into pieces, and forced through a nylon mesh into sterile medium 199. The spleen cell suspension was counted in a haemocytometer by the trypan blue exclusion method and diluted to 1×10^7 spleen cells ml⁻¹. The number of plaque forming cells (PFC) was measured according to a modification of Cunningham and Szenberg¹⁰. Three pieces of double-sided tape $\frac{1}{2}$ inch wide were laid across

a clean microscope slide (75 × 25 mm) dividing it into two equal areas. Two clean coverslips (22 mm square) were placed on the tape such that two edges of each coverslip were firmly attached to the tape and formed two shallow chambers. A mixture containing 88% spleen cells (1×10^7), 2% SRBC, 5% complement and 5% medium 199 was delivered by a syringe into the two chambers. These were sealed with vaseline and incubated at room temperature for 2 h. The plaques were counted using a light microscope. The number of plaques per million spleen cells was calculated from the number of plaques observed per μ l of the initial mixture used.

The same procedure was used to assay the secondary response (animals killed on days 8–14). Medium 199 was replaced in the mixture by developing antiserum (Microbiological Associates, Bethesda, Maryland No. 52-122). The number of plaques per million spleen cells was corrected by determining the sensitivity of the developing antiserum and by determining the number of plaques that occurred in spleen suspensions from non-antigen (SRBC) stimulated mice.

The mice were bled every 2 weeks to observe the erythrocytes for basophilic stippling and to determine packed cell volume. Serum was collected before death for haemolysin titration. One kidney was collected at necropsy and stored at -70°C for lead analysis. The other kidney was fixed in 10% buffered formalin for microscopic examination.

There was a reduction in the number of spleen cells producing 19S antibody in each dose of lead exposed mice (Fig. 1) but the decrease was most remarkable in the mice that received 1,375 p.p.m. lead. The peak response was on day 5 for all groups of mice but those given 13.75 and 1,375 p.p.m. lead also had a lag in their response as only a few plaques developed on day 4. The secondary immune response was markedly affected in all of the lead exposed animals. Even those mice that received the lowest lead dose (13.75 p.p.m.) had a significant decrease in the number of 7S plaque-forming cells. The control mice had 500 plaque-forming spleen cells on day 2 and the mice with 13.75 p.p.m. lead had 158 plaques per million spleen cells (Fig. 2). Furthermore, the mice on 137.5 and 1,375 p.p.m. lead had a lower response and a delay of 1 d in their peak response. They also remained much lower throughout the 7 d test period than did the controls. The mice that remained on 137.5 p.p.m.

Fig. 1 Primary immune response. The largest lead dose (1,375 p.p.m.) administered to the mice resulted in a five-fold decrease in antibody forming cells as compared to the controls. A 1 d lag in the antibody response occurred in two lead groups (13.75 and 1,375 p.p.m.). There was a highly significant difference in the means at days 3, 4 and 5 as determined by the analysis of variance. —, Control; ---, 13.75 p.p.m. Pb; - · -, 137.5 p.p.m. Pb; · · · · ·, 137.5 p.p.m. Pb (continuous); ———, 1,375 p.p.m. Pb.

lead throughout the study had fewer plaques, particularly IgG, than did those in which lead was discontinued at the time of inoculation of antigen (Figs 1 and 2).

All of the mice that received 1,375 p.p.m. lead exhibited basophilic stippling of the erythrocytes at 2 weeks of exposure. Basophilic stippling occurred in some of the mice that received 137.5 and 13.75 p.p.m. lead at 4 weeks and in all of those mice at 8 weeks. A few of the control mice had basophilic stippling at 6 and 8 weeks as the diet contained 1.12 p.p.m. lead. The packed cell volume was not significantly different for the various groups throughout the experiment.

As the sera collected at the time of death were haemolysed from the lead the mice received, the haemolysin titrations were quite variable and were considered inaccurate for comparing the circulating antibody titres with the number of plaque-forming cells.

Fig. 2 Secondary immune response. Day 1 represents that day after the second inoculation of the antigen (SRBC), or actually day 8 of the experiment. All lead exposed mice had a highly significant decrease in antibody forming cells as compared to the controls. The two larger doses of lead (13.75 and 1,375 p.p.m.) produced a delay of 1 d in their peak response. The antibody production was the lowest in those mice that were on lead continuously until death. There was a significant difference in the means at day 3 and 4 and a highly significant difference at days 1, 2 and 7 as determined by the analysis of variance. —, Control; ---, 13.75 p.p.m. Pb; — · —, 137.5 p.p.m. Pb; · · · · ·, 1,375 p.p.m. Pb (continuous); —, 1,375 p.p.m. Pb.

Histopathology disclosed a marked necrosis of the tubular epithelial cells in the renal cortex, especially near the cortical medullary junction, of the mice that were exposed to 1,375 p.p.m. lead. Many intranuclear inclusion bodies (stained with haematoxylin and eosin (H & E)) were in the renal epithelial cells of these mice for the 14 d period. The renal necrosis was not as extensive and there were fewer intranuclear inclusions in the mice that received 137.5 p.p.m. lead. Also, at day 14, the renal necrosis was not as severe and only an occasional inclusion could be found. There was moderate necrosis of the renal epithelial cells and an occasional intranuclear inclusion until day 5 in the mice that had been given 13.75 p.p.m. lead. From days 6–9, a narrow zone of mild degeneration and necrosis of the epithelial cells was in the cortex adjacent to the cortical medullary junction. Intranuclear inclusions were not observed by H & E stain. From days 10–14, the kidneys appeared to be normal and did not differ from the control kidneys. The Ziehl-Neelsen stain was used to confirm the acid-fast inclusion body that contained lead.

Table 1 Renal concentration of lead from mice that were exposed to lead for 56 days in the drinking water. The kidneys were collected 3 and 14 days after lead was removed from the water

Drinking Water p.p.m. lead	Mean p.p.m. of renal lead*	
	Day 3	Day 14
1,375	16.4 ± 1.97	11.0 ± 0.96
137.5	9.3 ± 0.62	6.7 ± 0.92
13.75	1.0 ± 0.13	0.9 ± 0.09
No lead (control)	0.6 ± 0.09	0.4 ± 0.05

*Wet weight

The kidneys were analysed for lead content by atomic absorption spectrophotometry using a micro-carbon furnace. The renal concentrations of lead at 3 and 14 d after exposure are listed in Table 1.

It has been shown¹¹ that lead acetate impairs hepatic phagocytic activity in rats but does not alter the primary or secondary immune response. More recently, however, lead acetate markedly reduced the serum antibody titre of pseudorabies virus in rabbits⁶. In the present study, lead acetate markedly decreased the number of cells forming antibody to SRBC suggesting that the decrease in circulating antibody is due to a decrease in antibody formation. Other environmental contaminants such as polychlorinated biphenyls⁸, cadmium⁹, mercury⁶, DDT (ref. 7), and sulphur dioxide¹² have also resulted in reduction of circulating antibody in animals.

Mice given sulphur dioxide for 135 d had an enhancement of antibody production but at 192 d the response was a suppression of antibody¹³. It was suggested that high concentrations of sulphur dioxide served as an adjuvant. Lead, however, is immunosuppressive and the larger amount accumulated results in a smaller quantity of antibody synthesised. The group of animals that continued to receive lead until killed had a very slight IgG antibody response and would be most susceptible to infectious agents.

The smallest dose in this study was 13.75 p.p.m. lead in the drinking water, so the mice were ingesting about 0.069 mg of lead d⁻¹. As approximately 10% of ingested lead is absorbed¹³, each mouse was actually receiving about 0.0069 mg of lead into its system each day. A significant decrease in antibody forming cells, particularly 7S, occurred at this dose. The adult human normally ingests 0.3 mg of lead d⁻¹ and 2 mg d⁻¹ can produce toxicity¹⁴.

The intranuclear inclusion bodies in the kidneys are composed of lead and protein¹⁵. They are an acute manifestation of lead poisoning and can occur as early as 24 h after a single intraperitoneal injection¹⁶. In the present study, mice that received 13.75 p.p.m. lead had intranuclear inclusions up to 5 d after removal from lead, but they were not identified thereafter by H & E staining. Also, the cellular degeneration and necrosis in the renal cortex from this group of mice was not as severe at day 6 and could not be recognised by day 11; indicating that there was apparently rapid removal of lead from the kidney after discontinuing administration of lead as well as regeneration of the damaged tubular epithelium.

We have shown that chronic exposure to lead produces a significant decrease in antibody synthesis, particularly IgG, indicating that the memory cell is involved. These results also indicate that the reduced antibody synthesis is responsible for the increased mortality from bacterial and viral diseases in animals that are chronically exposed to lead.

Dissociation between effects of nerve growth factor on tyrosine hydrolase and tubulin synthesis in sympathetic ganglia

TREATMENT of neonatal animals with nerve growth factor (NGF) promotes general growth and differentiation of the peripheral sympathetic nervous system. NGF markedly increases the outgrowth of axons and at the same time causes the appearance of many microtubules in electron-microscopic pictures¹. Moreover, as a manifestation of enhanced differentiation NGF produces a selective induction of tyrosine hydroxylase (TH) and dopamine β -hydroxylase in sympathetic ganglia². These two enzymes catalyse key steps in the biosynthesis of noradrenaline and are located selectively in adrenergic neurones³. In contrast, the third enzyme involved in the synthesis of noradrenaline, dopa decarboxylase (DDC), has a more general distribution and is not specifically regulated by NGF².

It is not clear whether the promotion of axon outgrowth and the accompanying increased formation of neurotubules results from specific induction of subunit synthesis⁴ or from regulation of the assembly of subunits. The purpose of this study was to resolve this question by examining simultaneously the effect of NGF on tubulin subunit content and TH activity.

NGF was prepared as the 2.5S subunit⁵ from mouse submaxillary gland. A single subcutaneous injection (10 mg per kg body weight) was administered to 5-d-old rats weighing 10–25 g. At appropriate times the animals were killed by a blow to the head and the superior cervical ganglia were removed under a binocular dissecting microscope. For determination of enzyme activity and protein content one pair of ganglia were homogenised in 0.5 ml 0.005 M Tris buffer containing 0.1% Triton in a power-driven glass homogeniser. The homogenates were centrifuged for 20 min at 10,000g at 4° C. Proteins⁶, TH⁶ and DDC⁷ were assayed; both TH and DDC assays were modified as described by Oesch *et al.*⁸. To determine tubulin subunit content 4–7 pairs of ganglia were homogenised in 0.5 ml of 0.05 M Na-pyrophosphate, 0.2 M NaCl, 1 M sucrose, pH 7 and supernatants were prepared as above. The presence of 1 M sucrose does not affect the absolute value of the colchicine binding activity in the extracts, but does increase the half life of that activity to approximately 220 h (ref. 9).

Figure 1a shows the time course of the changes in TH activity and protein content per pair of ganglia after a single injection of 10 mg per kg of NGF. A statistically significant ($P < 0.05$) increase in TH activity compared with untreated controls was detectable as early as 12 h after injection. The

maximum increase (350% of control) was reached at 48 h. Thereafter, the activity decayed gradually to 130% at 120 h. In contrast, a statistically significant ($P < 0.05$) increase of the protein content was not reached before 48 h and amounted to only 20%. The induction of TH was completely abolished if the animals were injected subcutaneously with 1.6 mg per kg of actinomycin D, 3 h before administration of NGF, and were killed 24 h later.

In contrast to the activity of TH, that of DDC changed virtually in parallel with the protein levels. The same is true for tubulin which did not change its specific activity over the whole period of 120 h (Fig. 1b).

In a further series of experiments the animals were injected daily with 10 mg per kg of NGF given subcutaneously for 5 consecutive days and were killed 24 h after the last dose. Under these experimental conditions the total activity of TH increased to 750% of controls, the specific activity to 375%. The corresponding values for tubulin were 275 and 140% respectively (Fig. 2).

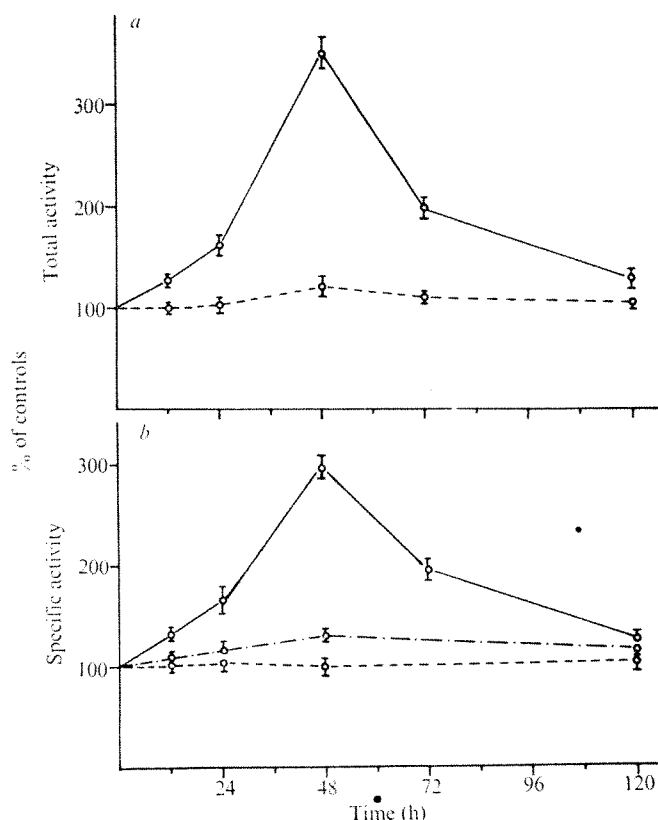

Fig. 1 Effect of a single dose of NGF on the levels of a, tyrosine hydroxylase (TH), ---, protein; b, tyrosine hydroxylase, ---, dopa decarboxylase (DDC), ----, tubulin in the rat superior cervical ganglia. The animals were injected subcutaneously with 10 mg kg⁻¹ of NGF 5 d after birth. TH activity and protein were determined in the supernatant after homogenising the ganglia in 0.005 M Tris-0.1% Triton X-100 and centrifuging the homogenate for 20 min at 10,000g. For the determination of TH activity the substrate (L-tyrosine) concentration amounted to 15 μ M, that of the cofactor (6, 7-dimethyl-5, 6, 7, 8-tetrahydropteridine) to 720 μ M. For the determination of DDC the substrate (L-³H-dopa) concentration was 1 mM, that of the cofactor (pyridoxal-5'-phosphate) was 0.24 mM and that of tranlycypromine was 1.2 mM. At the time of injection activity of TH was 0.3040 ± 0.019 nM dopa formed per h per pair of ganglia; that of DDC was 86.34 ± 6.04 nM dopamine formed per h per pair of ganglia. Tubulin was determined after incubation of the 10,000g supernatant with 8.3×10^{-6} M colchicine (2 Ci mmol⁻¹) for 90 min at 37° C by the filter assay of Borisy¹⁰. The specific activity of the tubulin in treated ganglia 48 h after injection was 3.6×10^{-5} d.p.m. bound per mg of protein. The values given represent the mean \pm s.e.m. of six or seven animals per group.

Fig. 2 Effect of repeated administration of NGF on level of TH and tubulin in the superior cervical ganglion. NGF was given subcutaneously on 5 consecutive days starting on the fifth day after birth. The ganglia were dissected 24 h after the last injection and treated as described in text. In the control animals the TH activity was 0.233 ± 0.007 nM dopa formed per h per pair of ganglia, the protein content was 14.8 ± 5.9 μ g per pair of ganglia, and the tubulin content was 5.52×10^{-4} d.p.m. bound colchicine per pair of ganglia. The values given represent the means \pm s.e.m. of six or seven animals per group. Shaded column, total activity; unshaded column, specific activity.

This study has shown that the effect of NGF on TH synthesis is quantitatively distinct after both single and multiple injections from the effect on tubulin synthesis. The dissociation of the appearance of increased numbers of neurotubules in electron microscopic pictures¹⁴ from any specific increase in the subunit content of the cells is consistent with the interpretation that NGF influences the assembly of preformed neurotubular subunits rather than enhancing their synthesis. This agrees with findings in other systems that outgrowth of cellular processes accompanied by the formation of microtubules does not require protein synthesis¹¹⁻¹³. Moreover, the induction of process formation in neuroblastoma cells by a glial-conditioned medium¹⁵ does not increase the tubulin content of the cells (F. S. and D. Monard, manuscript in preparation).

Reduced axoplasmic transport of choline acetyltransferase activity in dystrophic mice

MUSCULAR dystrophy has been regarded as a "primary degenerative myopathy"¹. But there is evidence from studies of both human muscular dystrophy and animal models of muscular dystrophy that the muscle disease may have a neural basis². The mechanism of the suspected neural disorder remains to be elucidated. Since there is independent evidence that in normal animals the trophic effect of nerve on muscle depends on intact axoplasmic transport³, we have initiated a study of axoplasmic transport in dystrophic mice. We have found a disturbance of axoplasmic transport of choline acetyltransferase activity in dystrophic mice.

Choline acetyltransferase (CAT) is the enzyme that catalyses the synthesis of the neurotransmitter acetylcholine⁴. In neural tissue, CAT is probably confined to cholinergic neurones⁵. It is likely that CAT, like other neural proteins, is synthesised in the nerve cell body and transported peripherally in the axoplasm to the nerve terminal^{6,7}. If a peripheral nerve is crushed by a ligature, CAT activity slowly increases on the proximal side of the constriction⁸. From the rate of accumulation of CAT activity, one can estimate the average velocity of proximo-distal axoplasmic transport of CAT⁹⁻¹¹. Here we present a study that shows a significant reduction in the average velocity of axoplasmic transport of CAT activity and a significant increase in the CAT activity in sciatic nerves of mice afflicted with an autosomal recessive form of muscular dystrophy¹². These findings may reflect a fundamental abnormality of axoplasmic transport of cholinergic neurones in dystrophic mice.

Male 129/ReJ dystrophic mice (dys/dys) with normal littermates (+/?), and normal retired breeders of known genotypes, (+/+) and (+/dys), were obtained from Jackson Memorial Laboratory, Bar Harbor, Maine. A ligature was placed on the right sciatic nerve, at mid-thigh level¹³. Animals were killed at various times following ligation and both sciatic nerves excised. One 1 cm length was cut from the middle of the non-ligated sciatic nerve. The 9 mm length of nerve immediately proximal to the ligature was divided into three 3 mm segments. The heat-labile CAT activity of the 8000g \times 10 min supernatant fraction of homogenised nerve segments was assayed with a simultaneous determination of the recovery of added purified mouse brain CAT activity. One unit of enzyme activity represents the production of 1 pmol of acetylcholine (ACh) from choline and ¹⁴C-acetyl coenzyme A per 3 mm length of nerve per min. We defined the accumulation of CAT activity as the increase in CAT activity within the 3-mm segment immediately proximal to the ligature. The initial CAT activity of the ligated nerve was estimated from the CAT activity of the non-ligated sciatic nerve. Values are presented as the mean \pm s.e.m. The statistical significance of values was determined by the Student *t* test.

Fig. 1 Accumulation of CAT activity in sciatic nerves of 6 to 7-week-old dystrophic mice (○) and normal littermates (●) at various times after unilateral sciatic nerve ligations. The number of littermate pairs (n), and the statistical significance (P) of the difference ($\Delta = \text{mean} \pm \text{s.e.m.}$) between the accumulation of CAT activity of the littermate pairs are indicated at each time of killing. Nerve segments were homogenised (1 mm per 100 μl) in all glass Duall tissue grinders with 0.2 M Tris-HCl (pH 8.5), 0.5 M KCl, 1 mM EDTA, 1 mg ml^{-1} bovine serum albumin (BSA) and 1% butanol-1 (v/v); the homogenates were centrifuged at 8,000g for 10 min. CAT activity was assayed in a 20 μl reaction mixture with a final concentration of 100 μM ^{14}C -acetyl-coenzyme A (specific activity 53 mCi mmol^{-1} , New England Nuclear, Boston, Mass.), 15 mM choline iodide, 0.1 M Tris-HCl (pH 8.5), 0.5 M KCl, 1 mM EDTA, 0.1 mM eserine sulphate, 0.5 mg ml^{-1} BSA, 0.5% butanol-1 (v/v) and the 8,000g supernatant fraction of 0.083 mm of nerve. The CAT activity reaction mixture was incubated 6 min at 38°C, the reaction was stopped with 10 μl of 2 N formic acid, and the product was extracted into octanone and measured as described by Glover and Green²⁵. Occasionally in parallel experiments, the CAT reaction product from non-ligated and ligated nerve samples was further characterised by high voltage electrophoresis²⁶. There was quantitative agreement between the radioactivity that migrated with the R_f of acetylcholine and the radioactivity extracted into octanone. In the case of both dystrophic and normal mice (1) omission from the homogenisation solution of the KCl resulted in the failure to retain 80% of the homogenate CAT activity in the 8,000g supernatant fraction; (2) incubation at pH 7.0 instead of 8.5 resulted in 30% less CAT activity, and (3) omission from both the homogenisation and incubation mixture of the EDTA, BSA, or butanol-1 resulted in 80%, 35%, and 10% less CAT activity, respectively.

In both the dystrophic mice and their normal littermates, CAT activity accumulated as a linear function of time for at least 3 d after unilateral ligation of sciatic nerves (Fig. 1). But the accumulation of CAT activity in dystrophic mice was only $48 \pm 5\%$ of that in normal littermates whose nerves had been ligated for the same period of time ($n = 40$, $P < 0.001$). The relative accumulation of CAT activity was computed from (1) the accumulation of CAT activity in the ligated sciatic nerve of the dystrophic mouse as a percentage of (2) the accumulation

in the normal littermate, for the 40 pairs after time zero in Fig. 1.

The accumulation of CAT activity also may be described by equations fitted by the method of least squares to the data in Fig. 1: $y_c = 122t_c + 10$ ($n = 46$, $r = 0.93$, $P < 0.001$) and $y_d = 68t_d - 6$ ($n = 46$, $r = 0.77$, $P < 0.001$) for control and dystrophic mice, respectively, where y represents units of CAT activity, and t represents time in days. The average velocity of transport of CAT activity was computed from the time it took to increase the CAT activity in the ligated nerve by an amount equal to the initial CAT activity. Solution of the equations for $y_c = 202$ units and $y_d = 231$ units (see below) yielded $t_c = 1.6$ d and $t_d = 3.5$ d. Thus the average velocity of proximo-distal transport was 3 mm per 1.6 d = 1.9 mm d^{-1} for the controls and 3 mm per 3.5 d = 0.9 mm d^{-1} for the dystrophic mice.

The difference between the rates of accumulation of CAT activity in the sciatic nerves of dystrophic mice and normal littermates was not due to a difference in the spatial distribution of accumulated CAT activity. For at least 3 d after ligation, the accumulation of CAT activity was confined to the 3mm segment proximal to the ligature in both dystrophic and normal mice (Fig. 2).

The CAT activity per unit length of non-ligated sciatic nerves from dystrophic mice was 14% more than that of the controls. The non-ligated sciatic nerves of the dystrophic mice and normal littermates in Fig. 1 yield 231 ± 5 and 202 ± 6 units CAT activity, respectively ($\Delta = 29 \pm 5$ units, $n = 46$, $P < 0.001$). Though we do not know what fraction of the soluble proteins of nerves is axonal in origin, we found an increase in the soluble proteins in nerves of dystrophic mice that paralleled the increase in CAT activity. In companion experiments, the right sciatic nerves of 6 to 7-week-old dystrophic mice and normal littermates were assayed for CAT activity; the left nerves were weighed, and the 8,000g supernatant fractions were assayed for protein¹⁴. The weights of non-ligated sciatic nerves from dystrophic mice were not significantly different from those of the normals (1.1 ± 0.1 compared with 1.2 ± 0.1 mg cm^{-1} , $\Delta = 0.1 \pm 0.1$, $n = 8$, $P > 0.5$). Because Tris-HCl buffer and BSA interfered with protein determinations, 0.2 M KPO_4 buffer (pH 8.0) was substituted for Tris-HCl buffer in all homogenisation solutions, and the BSA was omitted from the homogenisation solutions used for measurement of protein content. The CAT activity was 19% greater in the nerves of the dystrophic mice (250 ± 9 compared with 210 ± 15 units, $\Delta = 40 \pm 13$, $n = 8$, $P < 0.02$), and the soluble protein was 18% greater in the nerves of the dystrophic mice (53 ± 2 compared with 45 ± 3 $\mu\text{g cm}^{-1}$, $\Delta = 8 \pm 2$, $n = 8$, $P < 0.01$).

The differences in initial CAT activity and in the accumulation of CAT activity were not due to differences in the content of endogenous activators or inhibitors of CAT activity. In every case, the recovery of purified mouse brain CAT activity added to the 8,000g supernatant fraction of corresponding nerve segments was the same for dystrophic mice and their controls. Table 1 shows the recoveries of added CAT activity from samples of nerve segments 3 d after unilateral sciatic nerve ligation.

Table 2 presents the results of several experiments with different ages and genotypes of 129/ReJ mice. In the sciatic nerves of 9 to 12-month-old normal retired breeder 129/ReJ mice, neither CAT activity nor accumulation of CAT activity differed between the genotypes (+/dys) and (+/+). Therefore, normal mice (+/?) probably constitute a reasonable control population for the study of dystrophic mice (dys/dys). As controls for this study, we chose normal mice which were also matched for

Table 1 Recovery of added purified CAT activity from 8,000g supernatant fraction of sciatic nerve segments

Group*	Non-ligated nerve	Ligated nerve (mm proximal to ligature)†		
		6	3	0
Dystrophic mice	$120 \pm 8\%$ ‡	$107 \pm 6\%$	$115 \pm 10\%$	$98 \pm 15\%$
Normal littermates	$117 \pm 11\%$	$112 \pm 15\%$	$106 \pm 10\%$	$103 \pm 11\%$

* The ten pairs of dystrophic mice and normal littermates killed 3 days after unilateral ligation of the sciatic nerve included in Fig. 1.

† The number refers to the distance between the ligature and the 3-mm segments of nerves (see Fig. 2).

‡ The recovery of added CAT activity was calculated as a percentage of the purified CAT activity added. CAT activity was purified 99-fold (final specific activity 0.13 $\mu\text{mol Ach min}^{-1} \text{mg}^{-1}$) from brains of 6 to 7-week-old C57 BL/10J mice from Jackson Memorial Laboratory, Bar Harbor, Maine²⁷.

Table 2 Initial CAT activity and accumulation of CAT activity 1 d after unilateral ligation of sciatic nerves in various groups of 129/ReJ mice

Group	Phenotype	Genotype	Weight (g)	Sciatic nerve CAT activity (pmol Ach per min per 3-mm length of nerve)	
				Initial	Accumulation
Eight 3 to 4-week-old littermate pairs	normal	+/?	9.7 ± 0.7	168 ± 10	204 ± 19
	dystrophic	dys/dys	7.1 ± 0.7*	214 ± 19 ⁺	111 ± 31 ⁺
Ten 6 to 7-week-old littermate pairs	normal	+/?	20.2 ± 0.6	185 ± 12	164 ± 20
	dystrophic	dys/dys	10.2 ± 0.5‡	214 ± 8*	74 ± 12 ⁺
Eight age-matched (9 to 12-month-old) pairs of retired breeders	normal	+/?	25.1 ± 1.1	498 ± 20	149 ± 30
	normal	+/?	30.0 ± 1.2	500 ± 26§	157 ± 18§

Significantly different from their normal littermates with * $P < 0.02$, $^+P < 0.01$, or $^{\ddagger}P < 0.001$.

§ Not significantly different ($P > 0.5$) from the age-matched controls.

age (littermates). Table 2 shows that the increase in CAT activity and the reduction in the accumulation of CAT activity were evident in 6 to 7-week-old dystrophic mice whether one uses normal controls matched for age (littermates) or normal controls matched for body weight (3 to 4-week-old normal mice).

The neuronal mechanisms which are responsible for the increase in CAT activity and the reduced rate of accumulation of CAT activity in sciatic nerves of dystrophic mice remain to be elucidated. The reduced accumulation of CAT activity probably reflects a decrease in the amount of CAT activity that moves down the nerve axon towards the nerve terminal each day. This interpretation is compatible with the recent autoradiographic evidence that there is a reduction in the amount of protein slowly transported down nerves of dystrophic mice¹⁵.

The reduced rate of accumulation of CAT activity in nerves of dystrophic mice could be explained by (1) a decrease in the number of cholinergic fibres in the nerves¹⁶⁻¹⁸; (2) a decrease in the amount of CAT available for transport from nerve cell bodies; (3) a decrease in the velocity or in the fraction of CAT transported down nerve axons. But of these alternatives, only the latter one, by itself, can also explain the increase in initial CAT activity we observed in nerves of dystrophic mice.

Other abnormalities of peripheral nerves in dystrophic mice have been reported. Nerves of dystrophic mice have areas of abnormal myelination¹⁹, there are differences between the gel electrophoresis patterns of proteins from nerves of dystrophic and control mice²⁰, and the nerves from dystrophic mice are less able than nerves from controls to support muscle regeneration^{2,21}. Our finding of reduced axoplasmic transport of CAT activity in dystrophic mice may be indicative of a primary neuronal abnormality. It is possible, however, that our results reflect a disturbance of neuronal function that is secondary to muscle disease.

With regard to the latter alternative, our observation of early changes in CAT activity and its transport suggests that these changes are at least not late consequences of the muscle disease (Table 2). Also, the loss of muscle cells that accompanies murine dystrophy seems an unlikely cause of the increased CAT in nerves of dystrophic mice because there is evidence that the absence of contact of muscle cells with neurones results in lower CAT activity of the neurones^{22,23}. It is also unlikely that the loss of muscle cells is the cause of reduced axoplasmic transport of CAT activity since we have recently shown that section of the sciatic nerve in normal mice does not reduce the rate of axoplasmic transport of CAT activity proximal to the sectioned end (unpublished results).

The CAT activity of dystrophic muscle has been shown to be reduced compared with normal muscle²⁴. The reduction in dystrophic muscle CAT activity may be related to the reduction in axoplasmic transport of CAT activity documented here. Whether reduced axoplasmic transport of CAT activity is actually involved in the pathogenesis of the muscle abnormalities in murine muscular dystrophy remains to be determined. The neural abnormalities in dystrophic mice may be independent of the muscle disease. But as previously mentioned, there is evidence that the trophic effect of nerve on muscle depends on intact axoplasmic transport³. Therefore, it is possible that the muscle disease in dystrophic mice may be related to a disturbance of the axoplasmic transport of motor (cholinergic) neurones.

We thank Dr Richard Weinshilboum, Department of Pharmacology, Mayo Clinic, for his guidance in the adaptation of the CAT activity assay, and Drs Andrew Engel and Peter Dyck of the Department of Neurology, Mayo Clinic, for discussions of the pathology of muscle and nerve, respectively, in murine muscular dystrophy. This study was supported in part by research grants from the National Institutes of Health, Public Health Service.

Haemocyanin synthesis and the branchial gland of *Octopus*

MUCH is known about the biochemistry of haemocyanin¹ but little about how or where it is made. It has recently been suggested² on morphological grounds that in cephalopod molluscs it is synthesised in the paired branchial glands. Here we present the first experimental evidence to support this hypothesis and throw doubt on earlier theories that these organs are endocrine³⁻¹⁰.

The gland cannot be an analogue of the adrenal medulla or cortex^{8,9}. It seems to be without nerves^{2,11} and pharmacological and fluorescence tests for monoamines are negative; it contains no lipids¹² or steroids¹³ and the well-developed endoplasmic reticulum (ER) is not smooth². Although transient cardiostimulation can be produced by crude extracts, this effect is not dose-dependent or specific to the gland, is much less than that of 5-HT and is not sustained as are the responses to extracts of the vena cava¹⁴. Furthermore, transplants are not effective in preventing death after bilateral extirpation of the glands.

The most remarkable features of the *Octopus* branchial gland are the extraordinary development of rough-surface ER and the presence of vacuoles within the cell containing granules that look like haemocyanin². These findings have been independently confirmed and extended to a squid¹⁵. Martin and Muzii (unpublished observations) have also

observed large intracellular inclusions of what appear to be macromolecules in crystalline array. These were of two sizes, one of which agreed with Fernandez-Moran's estimate¹⁶ for the cephalopod haemocyanin molecule.

It has also been shown¹⁷ that large amounts of labelled leucine injected into the blood disappear rapidly and are taken up by the branchial glands. If the glands are haematopoietic they should take up amino acids and the rate of uptake should be severely reduced after the elimination of the glands. We set out to establish this in our first experiments.

To impair the function of the glands, we applied slivers of dry ice directly to their surface and froze them. Subsequent examination under the light microscope and EM revealed extensive necrosis and we estimated that less than 10% of the total gland mass remained functional after freezing. This method was adopted because previous experiments had shown that complete, simultaneous, bilateral excision is generally fatal.

Fig. 1 *In vivo* L-¹⁴C-leucine incorporation into the haemolymph proteins of *Octopus vulgaris*. Experimental animals, (a, ♂ 230 g; b, ♀ 165 g; c, ♂ 160 g; d, ♂ 620 g) had their branchial glands frozen. Control animals, (e, ♀ 155 g; f, ♀ 180 g; g, ♂ 170 g) were anaesthetised only. Counts were corrected for background.

Healthy *Octopus vulgaris* were anaesthetised with 3% urethane, the mantle septum was cut and the mantle reversed to expose the visceral mass. Control operations ($n=3$) stopped at this point but the experimental group ($n=4$) had dry ice applied to the glands. The mantle was turned back and the animals allowed to recover in a stream of seawater.

Twenty-four hours afterwards, each animal was again anaesthetised and a single dose of 5.0 μ Ci of L-¹⁴C-leucine in 0.4 ml 1 M Tris-HCl buffer (pH 7.5) was injected into the lumen of the branchial heart. Haemolymph samples of 200 μ l were withdrawn under anaesthesia from the contra-lateral branchial heart at varying intervals over a 54 h period; blood cells were allowed to sediment overnight and the protein content of the supernatant determined by the

Biuret method¹⁸ using BSA as a standard.

Radioactivity was measured in aliquots of whole haemocyanin and compared with the radioactivity in TCA-precipitated haemolymph proteins. Samples of whole haemolymph (100 μ l) were dissolved in 10 ml of InstaGel scintillation cocktail (Packard, Chicago) and TCA-precipitated protein was collected on glass fibre disks¹⁹ and counted in a toluene-based scintillation fluid containing 5 g l⁻¹ PPO and 0.2 g l⁻¹ POPOP. Results from both methods were in excellent agreement.

Figure 1 illustrates the effect of freezing the glands on the uptake of labelled leucine. Experimental animals showed almost no increase in activity throughout the entire period of the experiment yet, in spite of considerable individual variation (not obviously related to size or sex), animals of the control group all exhibited a high uptake of radioactivity into the blood protein.

Although haemocyanin represents the major protein constituent of *Octopus* haemolymph, to confirm that the radioactivity reflected the synthesis of haemocyanin rather than some other protein, we resorted to an immunological characterisation, using the Ouchterlony double-diffusion method on an agar plate²⁰ followed by autoradiography of the dried plate. Haemocyanin antibodies were obtained by intravenously inoculating rabbits with 10 mg pure octopus haemocyanin three times at 10 d intervals; serum was collected 1 week after the last inoculation. In preliminary experiments anti-haemocyanin serum was tested against purified haemocyanin, whole haemolymph and concentrated haemocyanin-free haemolymph. A single precipitation line showing a complete arc of identity developed between serum and haemocyanin and whole haemolymph. No precipitation line was formed with haemocyanin-free haemolymph even when it was concentrated eight-fold.

In Fig. 2a is shown a double diffusion plate stained with Amidoschwarz in which haemolymph from control and operated animals (I and IV) gave a strong positive reaction, each yielding a single precipitation line that was identical to that of purified haemocyanin (II and III).

Autofluorography of the plate, by exposing the Kodak recording film to the dry gel plate for 2 weeks, revealed that the radioactivity was localised in a single line corresponding to the control animals' haemocyanin-antibody

Fig. 2 Incorporation of L-¹⁴C-leucine into *Octopus* haemocyanin: immunoautoradiography. a, Amidoschwarz-stained immunodiffusion. Pure haemocyanin in wells II and III; radioactive haemolymph from control animal in well I; radioactive haemolymph from experimental animal in well IV; and anti-haemocyanin serum in well V. b, Autoradiography of a. Note the dark line indicating the radioactivity in the precipitation arc between wells I and V.

complex (Fig. 2b). There can be no doubt, therefore, that the amino acid is being incorporated into haemocyanin and that only in octopuses with intact branchial glands does labelled leucine get into the haemocyanin.

From this we conclude that the branchial gland of *Octopus* is undoubtedly involved in the biosynthesis of the respiratory pigment haemocyanin. Little is known about this process and it is hoped that the large size and accessibility of the branchial gland may make this gland invaluable for studying it.

Secretion-dependent uptake of extracellular fluid by the rat neurohypophysis

THERE is considerable evidence that hormone secretion from the neurohypophysis occurs by exocytosis of neurosecretory granules present in the nerve terminals¹⁻⁴. Exocytosis involves fusion of the granule membrane with the plasma membrane so that the entire soluble content of the granule is discharged into the extracellular space. Persistent hormone secretion does not lead to irreversible expansion of the plasmalemma of neurosecretory terminals, so the granule membrane must somehow be

retrieved after fusion. There is morphological evidence based on the use of electron dense markers in various preparations, that following exocytosis membrane is returned to the cell interior where it is present as microvesicles and larger cisternae⁶⁻¹⁰.

As large marker substances are taken into the nerve terminals, it seems likely that there ought also to be uptake of smaller molecules in proportion to their concentration in the external medium. If this is the case, the uptake of radioactive tracers might provide quantitative data on the magnitude of endocytosis occurring at actively secreting neuroendocrine terminals.

Neurohypophyses obtained from adult rats following decapitation were incubated in groups of four in 1 ml of oxygenated Locke solution¹¹ maintained at 37° C in a water bath. After 20 min, the solution was drawn off and immediately replaced by one containing: choline chloride, 150 mM; KHCO₃, 6 mM; CaCl₂, 2.2 mM; MgCl₂, 1 mM; glucose, 10 mM. ¹⁴C-Inulin (7.5 µCi ml⁻¹), ¹⁴C-mannitol (2.4 µCi ml⁻¹) or ¹²⁵I-albumin (2.4 µCi ml⁻¹, all three from Amersham) were present in the bathing fluid for the next 40 min. During the last 10 min of this second incubation, hormone release was evoked by raising the external KCl concentration to 56 mM, the choline chloride concentration being lowered to maintain constant osmolality. This incubation medium was then withdrawn and its oxytocin content determined in a rat bioassay¹². After stimulation, the preparations were washed for 150 min in Locke solution to remove the tracer molecules present in the extracellular spaces, the solution being renewed every 10 min. The neurohypophyses were then weighed, homogenised in 1 ml of HClO₄ 11% (w/v), centrifuged, and the radioactivity of the supernatant determined.

Fig. 1 Effects of calcium antagonists on mannitol uptake. Same experimental design as data of Table 1. □, Control uptake ($n = 4$); striped columns, stimulated preparations (56 mM KCl). Note absence of extra uptake of mannitol in preparations depolarised in presence of D600 (0.1 mM, third column $n = 6$) or Mn²⁺ (5 mM, fourth column, $n = 4$). Each column represents mean \pm s.e.m.

Exposure of neurohypophyses to the depolarising solution led consistently to an increased cellular uptake of extracellular marker substance. The results, summarised in Table 1, indicate that uptake is increased 3.0–5.4 fold in the stimulated preparations. The extra uptake of mannitol was greater than that of inulin or albumin but more experiments are needed to decide whether this difference is significant. The extra uptake could be caused either directly by a depolarisation-induced increase in the permeability to the tracer or indirectly as a result of secretion. The second hypothesis seems most likely because the extra uptake is abolished by including in the external medium either 5 mM manganous chloride or 0.1 mM of the organic calcium antagonist D600, (Fig. 1), both of which abolish

Table 1 Amount of radioactivity taken up by stimulated and control neurohypophyses

	Trapped radioactivity (c.p.m. per mg tissue)		Equivalent volume of extracellular fluid taken up during stimulation ($\mu\text{m}^3 \text{mg}^{-1}$)
	Stimulated preparations	Controls	
¹⁴ C-Mannitol	20.4 \pm 1.5 (8)	5.7 \pm 0.4 (4)	7.0 $\times 10^6$
¹⁴ C-Inulin	3.3 \pm 0.6 (6)	1.1 \pm 0.1 (5)	1.1 $\times 10^6$
¹²⁵ I-Albumin	4.1 \pm 0.2 (8)	0.75 \pm 0.1 (4)	1.1 $\times 10^6$

Preparations were kept 40 min in a Na-free Locke solution containing radioactive mannitol (0.015 mg ml⁻¹), inulin ($\sim 40 \text{ mg ml}^{-1}$) or albumin ($\sim 2 \text{ mg ml}^{-1}$). Stimulated neurohypophyses were incubated for the last 10 min in a high-K Na-free solution in presence of one of the extracellular marker substances. The Table shows the calculated uptake in control and stimulated preparations during the last 10 min of the incubation with radioactive marker. The difference in uptake between stimulated and control preparations is highly significant in all three cases (t test, $P < 0.001$). Each value represents mean \pm s.e.m. with the number of experiments in brackets.

calcium uptake induced by depolarisation of nerves¹³ and calcium-dependent hormone release from the neurohypophysis¹⁴. The view that uptake of extracellular tracer induced by depolarisation is secondary to secretion is supported by two other observations: first, both hormone release¹⁵ and tracer uptake are greater when secretion is evoked in a Na-free medium than when Na is present and, second, in Na-free media uptake of tracer induced by depolarisation increases linearly with tracer concentration in the external medium (Table 2).

These data are fully consistent with the hypothesis that, following exocytosis, membrane is retrieved by a process functionally similar to pinocytosis. On the assumption that uptake of tracer occurs without change in its concentration, it is possible to express the uptake in terms of a volume of extracellular fluid taken up and relate this to an equivalent volume of granules that must have undergone exocytosis. The data of Tables 1 and 2 give, for the three extracellular markers used, an average uptake of extracellular fluid equivalent to $3.1 \times 10^6 \mu\text{m}^3$ per mg tissue. In the same conditions, the amount of vasopressin and oxytocin released amounted to 90 milliunits, that is approximately 10% of the total neurohypophyseal hormone content of the glands believed to be contained in 2×10^{10} neurosecretory granules¹⁶. Assuming that release occurs solely by exocytosis, and taking 85 nm to be the mean radius of the core of the granules, the induced release should lead to a loss of $5.2 \times 10^6 \mu\text{m}^3$ per mg of tissue which is in surprisingly close agreement to the volume calculated from the uptake of extracellular markers.

If it is assumed, first, that both exocytosis and endocytosis involve spherical vesicles and, second, that membrane area is conserved, the relative volumes of fluid lost during exocytosis and gained during subsequent endocytosis should be in direct proportion to the ratio of the diameters of the vesicles involved in the two processes. Our data are consistent with membrane retrieval occurring through vesicles of diameter comparable to the granules undergoing exocytosis; but the data are not yet good enough to rule out other possibilities.

Morphological evidence supporting our conclusions was obtained by using the extracellular tracer horseradish peroxidase (HRP; Sigma, type II). HRP (2 mg ml⁻¹) had no effect on either resting levels of hormone secretion or secretion induced by depolarisation. In control experiments, following exposure to

Table 2 Dependence on the extracellular mannitol concentration of the secretion-dependent uptake of ¹⁴C-mannitol.

Mannitol concentration (mM)	Extra uptake in stimulated preparations (fmol mg ⁻¹)	Equivalent volume of extracellular fluid taken up ($\mu\text{m}^3 \text{mg}^{-1}$)
0.07	4.9 $\times 10^3 \pm$ 0.2 (8)	7.0 $\times 10^6$
1	67.7 $\times 10^3 \pm$ 9.7 (3)	6.8 $\times 10^6$
3	127.1 $\times 10^3 \pm$ 15.2 (3)	4.2 $\times 10^6$
5	317.4 $\times 10^3 \pm$ 11.7 (3)	6.3 $\times 10^6$

Fig. 2 Electron micrographs of neurohypophyses incubated in the presence, (a, c), or absence, (b), of horseradish peroxidase (HRP). Unfrozen sections (40 μ m thick) of glutaraldehyde-fixed specimens were treated to demonstrate sites of peroxidase activity¹⁷. a, Low magnification ($\times 7,500$) view of non-stimulated neurosecretory endings. Black HRP reaction product is present in the intercellular spaces, and in a few vacuoles within the cytoplasm (arrows). b, Stimulated neurohypophysis incubated in the absence of the tracer, to reveal endogenous peroxidase contained no HRP-tagged structures. The arrows indicate several membrane-bounded vacuoles ($\times 16,000$). c, Stimulated neurohypophysis. The arrows point to numerous peroxidase-labelled vacuoles. The size and location of the vacuoles are comparable to those shown in B ($\times 13,250$). * collections of microvesicles; sg, neurosecretory granules.

HRP for 40 min, the reaction product was mainly present in the extracellular space and very little was detectable in vesicles within the cytoplasm (Fig. 2a). In preparations that had been depolarised for 10 min (Fig. 2b and c) there was a variable degree of degranulation of neurosecretory endings and HRP reaction product was found in numerous membrane-bound vacuoles of a size (~ 100 nm radius) somewhat larger than that of the neurosecretory granules (~ 85 nm radius) seen within the endings. The vacuoles were preferentially localised near the plasmalemma. As previously reported⁵, microvesicles labelled with peroxidase, both coated and uncoated, could also be found but even after brief depolarisations their number was always low in proportion to the labelled vacuoles. As we found relatively few HRP-positive microvesicles, our results contrast with those of Nagasawa *et al.*⁵. We have no ready explanation for this discrepancy, but note that our experiments were performed in solutions free from sodium, leading thereby to a more powerful release reaction¹⁵. It may well be that two routes of endocytosis exist, and their relative importance may depend upon the intensity of secretion¹⁸.

Previous workers have described an extra uptake of calcium associated with depolarisation of the posterior pituitary^{14,19} and in view of our evidence for uptake of extracellular fluid it is clearly of interest to know how much of this extra entry of calcium might be accounted for by membrane retrieval and how much by other routes. In comparable conditions, the extra entry of calcium is 10–30 times as great as that of mannitol, indicating that only 3–10% of the calcium entry can be due to membrane retrieval.

Our results provide strong evidence that recovery from exocytosis includes membrane retrieval by a process that involves the indiscriminate uptake of extracellular fluid. The fate of the substances taken up is unknown; but it seems possible that the process of membrane retrieval may provide a route for the uptake of physiologically important substances into the neurone.

Food vacuole membrane in nutrient uptake by *Tetrahymena*

ALTHOUGH the ciliate protozoon, *Tetrahymena pyriformis* was first cultivated in sterile broth more than 50 years ago¹, and in chemically defined media more than 20 years ago² its uptake of nutrients in solution is poorly understood. For example, the part played by the food vacuoles is still unknown. The vacuoles seem to be essential for rapid cell multiplication in some media^{3–5}, but calculations show that the volume of the food vacuoles formed per unit time cannot account for the observed uptake of either acetate⁶ or nucleosides (present report). Previously, it was proposed that the mucous layer might be able to concentrate nutrients and thus increase their uptake⁷. I here present an alternative hypothesis.

Inclusion of insoluble material in the medium shortens generation times and induces formation of food vacuoles in *T. pyriformis*^{3–5}. The generation times are more than 40 h in particle-free, sterile-filtered proteose peptone broth, but only 6 h in this medium in the presence of particulate material (ferric or aluminium hydroxides, heat-denatured egg albumin, polystyrene beads, or the precipitate formed by heat sterilisation of the proteose peptone broth). The slowly growing cells contain less than three vacuoles per average cell, whereas the fast growing cells have 20–30 (ref. 3). These results suggest that particles induce formation of food vacuoles and that formation of food vacuoles is required for rapid uptake of one or more essential nutrients.

Data from growth experiments in media of known composi-

Fig. 1 Cell multiplication in populations of *Tetrahymena pyriformis* in the presence (a) and absence (b) of particulate material, Sephadex beads diameter approximately 1 μm . The nutrient medium was chemically defined except for addition of proteose peptone, final concentration 0.05%. The initial cell concentrations were 1,000 cells ml^{-1} . Each point represents the average of eight experiments. Figure reproduced from ref. 4.

tion allow the estimation of the contribution of the food vacuoles to the uptake of compounds which *Tetrahymena* cannot synthesise *de novo*, for example nucleosides⁸. Figure 1 shows cell doublings against time in the presence and absence of particles which induce the formation of food vacuoles. The estimate is based on a doubling time of 6 h in the presence of the particles, an observed rate of vacuole formation of one every 3 min, a measured vacuole diameter of 6 μm and a nucleoside concentration of 80 mg per l of medium⁴. From these values it has been calculated that in one generation time a cell of average volume about 27,000 μm^3 (ref. 9) makes vacuoles of which the total volume amounts to about 13,000 μm^3 . Assuming equal initial extracellular and intravacuolar concentrations, this volume contains about 10^{-12} g nucleosides. The cell requires, however, approximately 100×10^{-12} g nucleosides in order to double its content of nucleic acids¹⁰. Uptake of nucleosides through the cell surface is apparently insufficient to make up the difference, since cell multiplication is poor when food vacuoles are not formed due to the absence of particles (Fig. 1).

To account for the discrepancy, I propose that *Tetrahymena*, by some means other than uptake through its whole surface, can sweep nutrients from a volume of medium which is much larger than the sum of the volumes of the food vacuoles formed in the same time. It is unlikely that the stimulating effect of the particles is due to collision effects on the whole cell surface. This conclusion is based on results obtained in particle-containing media in which both cell multiplication and vacuole formation were greatly reduced in two sets of experimental conditions, namely in a mutant of *T. pyriformis*¹¹ containing no food vacuoles (unpublished experiments) and in the wild type after inhibition of vacuole formation with cytochalasin B (refs. 12, 13).

Since particles assist uptake of nutrients present in low concentrations, and neither the volumes of the vacuoles formed, nor entry through the whole cell surface can in any way account for the extent of this uptake, the major site of uptake under these conditions may well be the food vacuole membrane—especially while it is under formation and in open connection with the external medium. The oral structures maintain a strong current of fluid past the cytopharynx at the base of which the food vacuoles are formed. This current brings the membrane

of the forming food vacuole in contact with a relatively large volume of the extracellular medium and thus in contact with large amounts of nutrients. In support of this, it has been observed that food vacuoles collect Indian ink particles representing a medium volume at least 500 times as large as their own (L.R., H. E. Buhse jun., and K. Groh, in preparation).

Alternatively, nutrient uptake through the cell surface suffices for rapid multiplication in the absence of food vacuoles, when a generous supply of nutrients is maintained⁵.

The hypothesis presented here accounts for the experimental results obtained to date. Confirmation of its validity requires demonstration that food vacuole membrane is much more efficient than the rest of the cell surface in transporting such compounds as amino acids and nucleosides from dilute solution. This is possible in that reduced food vacuole formation is correlated with lengthened generation times in limiting media whether the scarcity of new vacuoles is due to lack of particles³⁻⁵, to inhibition of food vacuole formation by cytochalasin B treatment^{12,13} or to a temperature-sensitive mutation. The hypothesis reconciles the apparent conflict between vacuole volumes, nutrient concentrations and amounts of nutrients taken up. It also draws attention to a few so far neglected points in the discussion of the significance of the food vacuole in the uptake of dissolved nutrients by *Tetrahymena*.

Aerosol particles on tobacco trichomes

MARTELL¹ has described a plausible chain of events by which atmospheric radioactivity is incorporated into insoluble particles that are deposited in the lungs of tobacco smokers. The subsequent long exposure of the lungs to alpha activity is a strong candidate for the cause of bronchial cancer. Here we provide evidence for one of the steps in the sequence.

The accepted major sources of a radioactivity in the atmosphere are radon and its decay products, which condense by attaching themselves to sub-micron atmospheric particles. According to Martell, many such aerosols contact and are incorporated into the sticky tips of tobacco trichomes (spine-like protuberances on the leaves). To contact the trichome tips directly the smaller particles that carry most of the radioactivity must diffuse to the sticky, exudate-coated tips of the trichomes. Later, during tobacco curing, the sticky exudate polymerises to encapsulate the aerosols in highly insoluble particles. Thus,

when inhaled as part of tobacco smoke, the radioactive aerosols have long residence times in the deep lung.

Martell has shown that trichomes of cured tobacco are radioactive and that the most insoluble, filterable portion of tobacco smoke is the most radioactive. In support of Martell's inference that the radioactivity observed on trichomes comes from atmospheric aerosols, we present evidence that aerosols are on and inside trichome tips.

Trichomes from North Carolina flue-cured and Turkish air-cured tobacco leaves were examined in a Cwiskscan-100 equipped with a Kevex X-ray energy spectrometer. This instrument allows visual observation at high magnification and detection of elements heavier than neon in particles down to 250 Å in diameter. Silicon, sodium, chlorine, calcium and potassium were seen frequently (Fig. 1), iron and lead occasionally. Only potassium and calcium were seen regularly in all tips and stems equally. These known components of tobacco² mask attempts to observe them in sub-micron silicate aerosols.

Aerosols of > 0.5 µm diameter can be analysed individually on the surface of trichomes. These larger particles could be seen attached to most of the trichome tips of the North Carolina tobacco and half of those on Turkish tobacco. Of five individual particles analysed on North Carolina trichomes, four gave clear

signals from silicon; one was doubtful. Iron was detected in several particles. One 0.5 µm particle on Turkish tobacco contained chlorine. These compositions imply that the particles were silicate minerals and salt, respectively.

Trichome tips at positions where no exterior particles were visible showed silicon in half of the North Carolina samples. Portions other than the tips showed none. For Turkish tobacco sodium and chlorine were found on tips and stems. Silicon and lead were present in about half of the tips. Some of the silicon was associated with visible sub-micron particles.

In short, tips, like the particles on them, contain elements commonly associated with both continental and marine aerosols. The direct inference is that where individual particles are not seen, the signal comes from many tiny aerosols trapped within the exudate on the tips. This observation provides an experimental link in Martell's reasoning that radon daughter radioactivity precipitates on aerosols which diffuse to trichome tips and later become insoluble residues in tobacco smoke. Martell proved that the radon daughter radioactivity is present in trichomes; we have shown that the aerosols which normally carry this radioactivity are present in the tips.

We thank E. A. Martell and S. E. Poet for discussions and for the tobacco samples.

Phytochrome intermediates in freeze-dried tissue

PHYTOCHROME is a plant photomorphogenetic pigment existing in two forms, Pr and Pfr, interconvertible by light, which have absorption peaks in the red and far-red regions of the spectrum respectively^{1,2}. Intermediates between Pr and Pfr have been studied by several techniques *in vivo* and *in vitro* including flash photolysis^{3,4}, low temperature spectroscopy⁵⁻⁷ and measurement of the dark (d) reactions of intermediates that accumulate in conditions of pigment cycling⁸⁻¹⁰. The pathways Pr→Pfr and Pfr→Pr have been shown to be different, but, both pathways involve an initial photoreaction of the chromophore, followed by a series of dark reactions^{10,11}:

P698, P710, P650, P690 are intermediates having peak absorbance at 698, 710, 650 and 690 nm respectively; Pb1 and Px are intermediates having relatively weak absorption bands. I now report a technique enabling phytochrome intermediates to be studied *in vivo* at 0° C using a dual wavelength spectrophotometer.

It has been known for some time that complete photoconversion of phytochrome is not possible in dehydrated tissue or samples of phytochrome dried on to gelatin films¹²⁻¹⁵. Measurements have been made, however, either by slowly

scanning a complete spectrum or by restricting measurements to the wavelengths 730 v 800 nm used routinely for the phytochrome assay. Figure 1 shows differential absorbance changes that occur in a sample of freeze-dried dark grown *Pisum* epicotyl tissue. Using wavelengths 735 v 800 nm it is clear that Pr cannot be photoconverted to Pfr on exposure to actinic red light. Observations at 698 v 800 nm, however, demonstrate that high absorbance after actinic red light disappears in darkness. Similar measurements at the peak absorbance of Pr, 665 v 800 nm, show an increase in absorbance in darkness after actinic red light. This is interpreted as the phototransformation of Pr to the intermediate P698 and its reversion to Pr in darkness^{6,10}.

This conclusion is supported by the lack of any absorbance changes after actinic far-red light and the fact that the kinetics of the absorbance decrease at 698 nm and the absorbance increase at 665 nm are identical. It is therefore concluded that in freeze-dried tissue, Pr undergoes isomerisation of the chromophore and that this event is reversed in darkness. This situation is similar to that observed at -70°C *in vivo*¹⁰.

A similar experiment carried out with tissue freeze-dried with phytochrome in the Pfr form shows that a photoreversible reaction occurs on exposure to alternate actinic red and far-red light. A difference spectrum for this reaction is shown in Fig. 2. Compared with the normal difference spectrum of phytochrome photoconversion in hydrated tissue the absorption in the red region of the spectrum is low and is similar to that of the intermediate P650 produced on exposure of Pfr to far-red light at -196°C (refs. 6 and 10). I conclude that this photoreaction of Pfr in freeze-dried tissue is restricted to the phytochrome chromophore.

The behaviour of P650 on exposure to actinic red light is clearly different from Pr which produces the unstable P698 under these conditions of dehydration.

The effect of dehydration on phytochrome seems to be similar to that of low temperature. Low temperatures, however, not only restrict the conversion of Pr to Pfr and *vice versa*, but shift the absorption peaks of Pr and Pfr to longer wavelengths

Fig. 1 Recordings of differential changes in absorbance in a sample of freeze-dried dark grown *Pisum* epicotyl tissue (3 mm path length) at 0°C using a Perkin-Elmer 156 dual wavelength spectrophotometer. They demonstrate the production of the intermediate P698 and its reversion to Pr after actinic red light. Sample consisted of 1 cm third internode sections of *Pisum sativum* cv. Alaska seedlings 7 d old grown in darkness at 25°C were frozen in liquid nitrogen, freeze-dried for 36 h and kept over P_2O_5 in a desiccator at -20°C for 5 d. All manipulations were carried out under a dim green safelight. Intensity of actinic red light (660 nm) $1.2 \times 10^3 \mu\text{W cm}^{-2}$, far-red light (730 nm) $1.3 \times 10^3 \mu\text{W cm}^{-2}$.

Fig. 2 ●—●, Difference spectrum for the photoreaction that occurs at 0°C in a sample of *Pisum* epicotyl tissue (3 mm path length) freeze-dried after a saturating exposure to red light (●—●, $2 \times 10^{-3} \Delta A$). It demonstrates the photoreaction between the intermediate P650 and Pfr. ---, Difference spectrum for the photoconversion of phytochrome in a freshly collected sample of *Pisum* epicotyl tissue at 0°C (l---l, $1 \times 10^{-2} \Delta A$).

(for example, the peak absorption of Pfr shifts from 732 nm at 0°C to 744 nm at -196°C)⁸. Dehydration does not seem to bring about such large wavelength shifts. This means that the absorption characteristics of intermediates measured in this way can be used for comparison with action spectra of physiological responses in which they have been implicated. The dehydrated tissue containing Pr and Pfr shows photoreactions which are interpreted as being restricted to the chromophore of phytochrome. Controlled rehydration experiments are being conducted to study the reactions of the isomerised chromophore and protein. The use of this method should enable a critical analysis of phytochrome intermediates to be made without the difficulties associated with the use of low temperatures. Furthermore, freeze-dried samples have been demonstrated to be stable even when stored for several days in darkness at room temperature.

Chemical and biological degradation of waste plastics

BRITISH domestic refuse can mainly be divided into ash, cinders, paper, cardboard, glass, metals, plastics and organic matter^{1,2}. The relative amounts of each component have varied over the years: ash and cinders have decreased while paper, cardboard, glass, metals and plastics have increased, because of their widespread use in 'throwaway' packaging.

Cellulosic wastes present few problems during disposal, while glass and metal can be reused or recycled. Plastics, however, are less easily dealt with. They will not rot away in the soil or during composting, and they also present problems on incineration³⁻⁵. Some plastics waste can be recycled at source within industry but at present it would be uneconomical to reuse the plastics in town waste, and even in industry there is little demand for the reuse of plastics⁶.

It is generally agreed that most of the synthetic polymers in use today resist biodegradation but that the plasticisers, used to modify the physical properties of some plastics, are biodegradable⁷⁻⁹. As most of the plastics in town waste are unplasticised⁵, they remain unchanged after all but the most destructive disposal processes, the advent of plastics has called into question the idea of 'microbial infallibility'¹⁰. If a completely new biodegradable plastics were produced it would be more expensive^{11,12} than present plastics because of the limited scale of manufacture. On the other hand, the recent production¹³ of photodegradable plastics does not take into account the fact that the majority of town waste is still used for landfilling, and is therefore not exposed to sunlight.

Town waste at present contains 1.2% by weight (5% by volume) of plastics. About 70% of these plastics are derived from packaging: they comprise (by weight of packaging plastics): 66% polyethylene, 16% polystyrene, 8% polypropylene, 4% polyvinyl chloride, 3% thermosets, and 3% miscellaneous⁵. Our aim was to develop a process for converting waste plastics to protein. We hoped to do this by chemical degradation followed by fermentation, and a literature survey suggested that oxidation¹⁴⁻¹⁶ would be an effective degradation method. Indeed, previous experiments^{9,17} had shown that the oxidation products of polyethylene could support the growth of many thermophilic fungi and actinomycetes. We tried the effect of several oxidising agents on polyethylene, the commonest packaging plastic, and as a result of our experiments chose nitric acid (reaction conditions given in Figs 1-3). We found that the nitric acid could be recovered by distillation and reused. We were able to oxidise four 10 g batches of

polyethylene with one 250 ml batch of 86% v/v nitric acid.

We then took some discarded plastics packages, identified the plastics from their behaviour on burning⁵, and refluxed each of them with 86% v/v HNO₃. The polyethylene articles were completely dissolved after 23 h reflux, while polystyrene, polypropylene and polyvinyl chloride left residues.

We identified some of the oxidation products by gas chromatography. Oxidised polyethylene consisted of a mixture of straight-chain dicarboxylic acids containing from six to 12 carbon atoms; other components were present in trace amounts. Oxidised polystyrene consisted of two major components comprising 95% of the products. Oxidised polypropylene contained 14 components, seven of which were identified as dicarboxylic fatty acids containing 3,4,5,7,8,9 and 12 carbons. Polyvinyl chloride resisted oxidation by nitric acid.

We carried out experiments to determine whether the plastics oxidation products could support microbial growth. Nineteen thermophilic fungal species were incubated, in the conditions described in Fig. 1, with K⁺ salts of oxidised polyethylene as carbon source. (Previous experiments¹⁷ had shown that better growth was obtained on the K⁺ salts than on the dicarboxylic acids.) Little growth was obtained in the mineral salts alone, but several fungi grew well in the media containing the oxidised polyethylene. Three mesophilic fungal species cultured under the same conditions (but at 27° C) produced greater cell weights than did the thermophiles. Dry weights obtained per 50 ml of culture were: 34.2 mg for *Mucor* sp., 29.0 mg for *Penicillium* sp.,

Fig. 1 Growth of thermophilic fungi on oxidised polyethylene. Polyethylene (10 g, ICI, Alkathene) was refluxed with 200 ml 60% v/v HNO₃ for 24 h. The oxidation mixture was cooled, diluted with water, then extracted into diethyl-ether. The ether extracts were bulked, washed with water, evaporated and the resulting dicarboxylic acids converted to their K⁺ salts by addition of 250 ml of 0.2 M KOH.

The K⁺ salts were incorporated at a 1.0% v/v level in 50 ml of sterile Eggins and Pugh¹⁸ mineral salts solution (without added yeast extract or L-asparagine) in 250 ml conical flasks. The medium was adjusted to pH 6.4 and inoculated with 2 mm disks of thermophilic fungi⁹ on agar. Two replicates were made at each temperature (40° C and 48° C), and after incubation, the mycelia were filtered off, washed with boiling distilled water and dried to constant weight. Controls consisted of fungi incubated with mineral salts without added oxidation products.

The figure shows the mean mycelial weight, minus the weight obtained in the controls, of the following fungi: 1, *Malbranchea pulchella* var. *sulphurea*; 2, *Cephalosporium* sp. 3, *Mucor pusillus*; 4, *Sporotrichum thermophile*; 5, *Humicola grisea* var. *thermoidea*; 6, *Humicola lanuginosa*; 7, *Mucor miehei*; 8, *Talaromyces duponti*; 9, *Talaromyces emersonii*; 10, *Thermoascus aurantiacus*; 11, *Aspergillus fumigatus*; 12, *Chaetomium thermophile* var. *coprophile*; 13, *Chaetomium thermophile* var. *dissitum*; 14, *Humicola insolens*; 15, *Stibella thermophila*; 16, *Myriococcum albobasidium*; 17, *Humicola stellata*; 18, *Thielavia thermophila*; 19, *Torula thermophila*. ■, 40° C; □, 48° C.

Fig. 2 Growth of mesophilic bacteria on the oxidation products of four plastics packages. Ten grams of each of the four plastics packages, 1, 'Marks and Spencer' white polyethylene bag; 2, 'Squezy' polyethylene detergent bottle; 3, 'Lancashire Hygienic Dairies' polyethylene milk bottle; and 4, 'Ovothrm' polystyrene (non-expanded) egg carton were refluxed for 24 h with 250 ml of 86% v/v HNO_3 . The oxidation mixtures were allowed to cool, then converted to their K^+ salts by adding the following volumes of 60% KOH: 1, 260 ml; 2, 260 ml; 3, 267 ml; 4, 210 ml. The K^+ salts of each oxidised plastic were incorporated at a 4.0% v/v level into a sterile nutrient salts solution after Millipore filtration. The culture medium contained: K_2HPO_4 1.0 g; KCl 0.5 g; $(\text{NH}_4)_2\text{SO}_4$ 0.5 g; MgSO_4 0.2 g; yeast extract 0.5 g; distilled water to 1.0 litre. Flasks containing 100 ml of this solution were inoculated with standard amounts of one of four bacterial cultures, A1, A2, M1, M2, and incubated at 25° C for 6 d with shaking in a Gallenkamp Orbital Incubator. Controls consisted of bacteria incubated with mineral salts without added oxidation products. After incubation, the bacteria were centrifuged off and their dry weights determined. The spent culture medium was examined for the presence of unused oxidation products (Fig. 3). C, Control; 1, polyethylene bag; 2, polyethylene detergent bottle; 3, polyethylene milk bottle; 4, polystyrene egg carton.

and 28.9 mg for *Dicoccum* sp.

Four mesophilic bacterial species (A1 and A2 isolated from the atmosphere; M1 and M2 isolated from soil) were cultured on the K^+ salts of the oxidation products of the plastics articles listed in Fig. 2. In every case the biomass exceeded that obtained in the controls, and examination of the culture medium showed that A1 and A2 removed all the polyethylene oxidation products, M1 removed 31% and M2 removed 21%. The low removal by M1 and M2 was improved by increasing the initial concentration of the oxidation products in the medium to 25% v/v: 7 d incubation then resulted in 82% and 83% removal by M1 and M2 respectively.

To obtain protein for analysis we grew 5 l batches of A1 and A2 on the K^+ salts of the oxidation products of a polyethylene milk bottle. During culture we removed a 100 ml sample each day and determined its content of oxidation products (Fig. 3) and bacterial cells: 95% of the oxidation products were removed, and the yield of bacteria reached a maximum, within 2 d. Average dry weights of 1.5 g per 5 l of each organism were obtained after 2 d growth, and the protein contents of A1 and A2 were 38.3% and 46.4% of their respective dry weights. The proteins (Table 1) contained all the essential amino acids except (for A2) methionine. They are potentially valuable as a food, although feeding trials and toxicity studies would be required to confirm this.

Higher yields of biomass were obtained from the oxidation products of polyethylene than from those of polystyrene or polypropylene. Yields (g dry weight per 100 g of plastic after 3 d growth) of A1, A2, M1 and M2 were: 43, 39, 28 and 23 respectively from polyethylene; 6, 13, 10 and 4 respectively from polystyrene; and 10, 7, 4 and 2 respectively from polypropylene. Biomass yields (g per 100 g of polyethylene) of 176, 120, 80 and 70 respectively were obtained from the first four thermophilic fungi listed in Fig. 1 after 19 d growth at 40° C. As sources of single-cell protein, fungi have three advantages over bacteria: they are easier to harvest, they have a lower nucleic acid content, and they lack a toxic lipopolysaccharide cell wall.

Although we have separated the plastics from other components of rubbish before oxidation, it is not necessary to do so. We have oxidised samples of mixed rubbish of similar composition to that of town waste, and have grown microorganisms on the oxidation products. We are not seriously proposing the oxidation of mixed town waste, but our experiments do indicate that nitric acid oxidation is effective even when the plastics have other materials mixed with them.

Table 1 Amino acid composition of protein obtained from bacteria A1 and A2 grown on polyethylene oxidation products—comparison with composition of other proteins

Protein	Essential amino acids (g/100 g protein)										Nonessential amino acids (g/100 g protein)						
	His	Ile	Leu	Lys	Met	Phe	Thr	Trp	Val		Ala	Arg	Asp	Cys	Glu	Gly	Pro
Organism A1	2.1	5.6	9.5	6.7	0.4	3.6	5.5	4.0	7.7		11.7	5.6	9.3	—	10.3	9.3	4.9

Protein was extracted from freeze-dried cells as follows^{20,21}. Approximately 100 mg of cells were weighed into a plastic 100 ml centrifuge tube, and 40 ml of 5.0% v/v trichloroacetic acid added. After standing for 30 min at 5° C the cells were centrifuged (all centrifugations carried out at 10,000 r.p.m. for 10 min in a Martin Christ High-Speed refrigerated centrifuge, model Zeta), and the supernatant discarded. The residue (R1) was incubated for 30 min at 40–50° C with 60 ml of 75% v/v ethanol/water, centrifuged, and the supernatant discarded. The residue (R2) was incubated for 15 min at 40–50° C with a mixture of 20 ml 75% v/v ethanol/water and 20 ml diethylether, centrifuged, and the supernatant discarded. The residue (R3) was incubated for 30 min at 100° C with 40 ml of 5% v/v trichloroacetic acid, centrifuged, and the supernatant once more discarded. The resulting residue (R4) was washed twice at room temperature, first with 40 ml of ethanol which had been acidified with sufficient HCl to give a final concentration of 5 m mol l⁻¹ then with 40 ml of diethylether. Each washing was removed by centrifugation. The final residue was dried in air, weighed, and calculated as a percentage of the dry weights of bacterial cultures A1 or A2. Amino acids were analysed using a JEOL JLC-6AH Aminoacid Analyser after hydrolysing 2.0 mg of each protein in 3.0 ml of 6.0 M HCl for 18 h at 105° C, in a sealed tube. Tryptophan (destroyed by acid hydrolysis) was determined by dissolving unhydrolysed protein in sufficient 0.1 M NaOH to give an extinction of 0.2–0.5 at 250 nm, then determining the absorption at four wavelengths²².

Fig. 3 Utilisation of polyethylene oxidation products by mesophilic bacterium A1. Four polyethylene milk bottles (44.5 g) were refluxed for 48 h with 890 ml 60% v/v HNO_3 , allowed to cool, and converted to their K^+ salts by addition of 60% KOH to give a final volume of 2.5 l. Two hundred millilitres of this solution were sterilised by Millipore filtration and added to 5 l of nutrient salts (Fig. 2) in a Biotec FL 110 fermenter (autoclaved at 15 lb in^{-2} for 20 min). The fermenter was inoculated with 2.0 ml of a 24 h broth culture of bacterium A1, and incubated with vigorous aeration for up to 6 d at 25° C. Each day a 100 ml sample was removed aseptically, centrifuged, and the bacterial cells dried and weighed. The supernatant was examined for the presence of unused polyethylene oxidation products as follows: it was acidified with concentrated HCl to pH 2.0, extracted with 2 × 100 ml diethylether, the ether extracts bulked, dried over anhydrous Na_2SO_4 , filtered, and evaporated to dryness. The dry oxidation products were converted to their dimethyl esters¹⁹ (for gas chromatography) by boiling for 3 min with 5.0 ml of 14% boron trifluoride-methanol complex (British Drug Houses). The reaction was stopped by addition of 20 ml water, and the esters extracted into 2 × 50 ml diethylether and evaporated to dryness. The esters were dissolved in 0.5 ml chloroform, and 1.0 μl samples injected on to the gas chromatograph. Gas chromatography was carried out on a Perkin Elmer F11 (Mark 2) dual column gas chromatograph equipped with dual flame ionisation detectors. The instrument was fitted with glass columns, 6 feet long and 3 mm internal diameter, packed with diethylene glycol succinate, 20% w/w on Chromosorb W, HMDS, 80–100 mesh. Chromatography was carried out isothermally at 165° C, with an injection port temperature of 270° C and a carrier gas (nitrogen) flow rate of 20 ml min^{-1} . Gas pressures used were: nitrogen, 40 lb in^{-2} (270 kN m^{-2}); hydrogen 20 lb in^{-2} (135 kN m^{-2}); air 30 lb in^{-2} (202 kN m^{-2}). Peak assignments were made by comparing their retention times with those of authentic dimethyl ester standards: dimethyl malonate and dimethyl sebacate (Sigma, London), dimethyl succinate, dimethyl glutarate and dimethyl suberate (Ralph N. Emanuel, Limited). —, 0 h; ---, 48 h.

We thank P. Hilling for gas chromatographic advice; Dr G. N. Smith for chemical advice; Joan L. Ward for amino acid analysis; Angela Martin for technical assistance; and the University of Manchester Department of Medical Illustration for preparing the figures.

Haidinger's brushes and predominant orientation of collagen in corneal stroma

WHEN a source of bluish light, such as the sky, is viewed through polaroid glass or other polarising material, a characteristic figure known as Haidinger's brushes is fleetingly seen at the fixation point by most observers. The 'brushes' are shaped like an hourglass, yellow and darker than the surround, and are orientated with their long axis at right angles to the transmission plane of the polaroid. On either side of the brushes are light blue areas which are brighter than the surround: by some observers they are seen more clearly than the brushes themselves. If the polaroid is rotated, the brushes rotate with it in the same direction, and this manoeuvre prevents the figure from fading.

It is generally agreed that Haidinger's brushes result from the absorption of blue light by the pigment of the macula lutea^{1–3}. If the macular pigment, which absorbs maximally in the wavelength range 430–490 nm (refs 2, 4) is dichroic radially, then linearly polarised light will be absorbed about the diameter of the macula which lies at right angles to its plane of polarisation, producing a yellow region of diminished brightness with intervening blue areas occurring as a contrast effect. Nevertheless, Shurcliff⁵ argued on the basis of the appearance of the brushes with circularly polarised light that the accepted explanation of their causation might be wrong. According to Shurcliff, right-handed, circularly polarised light produces an oblique upward-to-the-right orientation of the brushes in each eye and left-

handed light produces an upward-to-the-left obliquity irrespective of the orientation of the circular polariser. Brindley³ has suggested that the effect of circularly polarised light could be explained if any of the optical media of the eye such as the cornea were birefringent with axes vertical and horizontal.

I have repeated Shurcliff's observations using quarter wave plate compensators as a source of circularly polarised light, but have been unable to confirm his findings either in my own eyes or in those of any subject whom I have so far examined. I have, however, found that a quarter wave plate for yellow light ($\lambda = 575$ nm, retardation checked by the method of de Sénarmont and with a Babinet compensator) consistently produces in persons, including myself, who are able to see Haidinger's brushes clearly, a reversal of the figure so that its long axis lies at right angles to its previous direction. This reversal is most evident when the transmission plane of the polaroid is vertical or horizontal, and the $\frac{1}{4}\lambda$ plate is interposed between the polaroid and either eye with its slow direction in the upward-and-outward diagonal. When the $\frac{1}{4}\lambda$ plate is inserted accurately in the upward-and-inward diagonal the figure disappears. A $\frac{1}{2}\lambda$ plate, on the other hand, produces reversal in the upward-and-inward diagonal and disappearance in the upward-and-outward diagonal.

These findings are explained if the collagen in the corneal stroma is predominantly orientated in the upward-and-outward diagonal—a view which agrees with earlier work^{2,6} on birefringence in the visual pathway. Collagen is positively birefringent with its optical axis lengthwise, so that its slow direction is along the length of the fibre. It is the only substance in the optical path that is sufficiently birefringent to influence the orientation of the figure significantly. Reversal will occur when the combined retardation of collagen and wave plate is near to half the wavelength of blue light, while disappearance will result from the circular or near circular polarisation occurring when the combined retardation is approximately a quarter or three quarters the wavelength of blue light.

To estimate the actual retardation produced by the corneal collagen in the upward-and-outward diagonal in my own eyes, I observed the effects of introducing into the visual path one or more compensators made from thin commercial polythene with a retardation of $\frac{1}{12}\lambda$. With the slow direction of the compensator in the upward-and-inward diagonal, that is, in the subtraction position with respect to the corneal collagen, the definition of the figure was enhanced by a retardation of $\frac{1}{12}\lambda$ and returned to normal with a retardation of $\frac{1}{6}\lambda$. These findings are compatible with a retardation due to the collagen of approximately $\frac{1}{12}\lambda$ (48 nm). A $\frac{1}{12}\lambda$ compensator in the upward-and-outward diagonal should, then, give the same combined retardation ($\frac{1}{6}\lambda$) as a $\frac{1}{4}\lambda$ compensator in the upward-and-inward diagonal, and so cause the figure to disappear.

This was found to be the case. It is now possible to explain more fully the results obtained with $\frac{1}{4}\lambda$ and $\frac{1}{2}\lambda$ plates. A $\frac{1}{4}\lambda$ plate in the addition position produces a combined retardation of $\frac{1}{2}\lambda$ which is approximately $\frac{2}{5} \times$ the wavelength of blue light giving reversal of the figure, and in the subtraction position a combined retardation of $\frac{1}{6}\lambda$, that is, $\frac{1}{5} \times$ the wavelength of blue light causing disappearance. A $\frac{1}{2}\lambda$ plate produces in the subtraction position a combined retardation ($\frac{5}{12}\lambda$) equal to $\frac{1}{2} \times$ the wavelength of blue light giving reversal, and in the addition position a combined retardation ($\frac{7}{12}\lambda$) equal to $\frac{3}{4} \times$ the wavelength of blue light causing disappearance.

A class experiment was conducted to determine the prevalence of a preferential orientation of the corneal collagen. One hundred students were asked to visualise Haidinger's brushes using polaroid and to report the effect on their orientation of a $\frac{1}{4}\lambda$ plate made from three layers of polythene. Eighty-three students were able to see the brushes, and of these 83% (69 students) obtained reversal with each eye when the slow direction of the $\frac{1}{4}\lambda$ plate was in the upward-and-outward diagonal and disappearance with the plate in the opposite diagonal. Because the subjects were not used to making such observations, these results may be regarded as confirmation of a

predominant upward-and-outward direction for the collagen bundles in the cornea. Recent authors⁷⁻⁹ have stated that the corneal collagen is randomly arranged, although Kokott's¹⁰ reconstruction of the superficial layer of the stroma shows a mainly oblique direction with an apparent preponderance in the upward-and-outward diagonal. It may be significant that the predominant orientation shown by the present study is in the line of pull of the tendons of the superior and inferior oblique muscles of the eye.

The apparent heaviness of colours

EARLY this century, E. Bullough¹ showed that some combinations of colours, one above the other, are chosen as more 'natural' than other combinations, which tend to look top heavy. Various methods of measuring the apparent weight of colours were subsequently devised: Bullough's preference method, tests in which the weight of coloured blocks was judged either visually or directly by hand^{2,3,4}, and the 'weighing' of half-inch circles of coloured paper at either end of a simulated balance arm with an adjustable fulcrum⁵. There was general agreement that red and blue were the heaviest colours, yellow the lightest. But no statistical evaluation was used in the earlier work; and as the colours were surface-illuminated, the effect of colour was easily confounded with that of brightness. In fact, most investigators considered that brightness was probably a crucial factor. In the present study, an adaptation of Monroe's procedures, the effects of colour and brightness were investigated separately using larger transilluminated stimuli, with brightness carefully controlled. Our results show that the effect is independent of brightness. Coloured circles, equal in subjective brightness, differ considerably in apparent weight, while achromatic stimuli which differ in brightness are not consistently different in weight.

The display as seen by the subjects is shown in Fig. 1. Two circular holes, 10 cm in diameter with 30 cm between centres, were cut in a matt black screen. The holes were covered by ground glass, on to which the stimuli were back-projected by two slide projectors. Between the circles was a horizontal slit along which the subject could move a small luminous pointer to the 'balance point', by turning a knob below the board. The display was positioned vertically in front of the subject in a dark cubicle, so that his eyes were about level with the stimuli and the control knob was within easy reach. Movements of the pointer were recorded on an oscilloscope screen, unseen by the subject.

We tested the effects of colour in the absence of brightness differences, and the effects of brightness in the absence of colour differences. In order to simplify the procedure, each of the test stimuli was individually 'weighed' against a white stimulus of constant brightness. For the colour experiment five colours were used: Red, Orange, Yellow, Green, and Blue (Kodak

Fig. 1 The display as seen by the subjects.

Wratten filters, Nos 25, 22, 12, 58 and 38A, respectively), all adjusted to be equal in subjective brightness to the standard. For the brightness experiment white stimuli of four different brightness levels were used, covering a 25-fold range in physical intensity.

Each colour was presented eight times and each brightness level four times in the course of a testing session on one subject, giving 56 'weighings'. The brightness stimuli were mixed in amongst the colour stimuli and the whole order was randomised, with the constraint that each stimulus should appear equally often on the left and right of the display. The order was changed for different subjects to eliminate possible order effects. Medians of the judgements made to each stimulus type were used in the comparison.

Ten men and ten women took part in the experiment. All were Cambridge undergraduates, none of whom had any previous knowledge of the phenomenon being studied. Each subject was given the following printed instructions at the start of the session.

"The apparent weight of colours. Pictures are often said to have a centre of gravity, perhaps determined by the way the different colours are arranged. Early this century, those investigating the psychology of aesthetics had the idea that colours have weight. This is an experiment to test that idea.

Imagine the slit joining the two circles to be a rigid bar connecting two heavy illuminated spheres, and supported by the luminous pointer as a fulcrum. By turning the knob, move the pointer along the slit to a position about which the two spheres appear to be exactly balanced in weight. There are no right or wrong answers, so please do not feel that you need to take a long time to make these judgements."

No practice examples were given, though the subjects were encouraged to spend more time over the first few judgements so that they should get the idea. When the subject indicated, for each stimulus pair, that he was satisfied with the position of the pointer, this was recorded, and the next pair presented.

With the coloured stimuli most subjects had little difficulty in making these unusual judgements, although a few said that they did not accept the metaphor of 'weight', and were simply placing the pointer where it looked best. With the stimuli of different brightness the subjects appeared more unsure of what to do, and their judgements were rather less reliable.

To evaluate the results, the position of the pointer was expressed in terms of the displacement from the mid-point towards the test stimulus, positive displacements thus indicating

Table 1 Median displacement of pointer from mid-point towards the test stimulus

Colour	Yellow	Green	Blue	Orange	Red
	0.9	1.9	1.9	2.1	3.8 cm
Brightness*	-0.8 0.2	-0.4 0.4	+0.3 0.2	+0.7 0.3 cm	

*Brightness given in log-foot-lamberts relative to standard

Table 2 Average ranks attributed to each colour

	Red	Blue	Green	Orange	Yellow
Men	0.70	1.65	2.25	2.10	3.30
Women	1.05	1.75	1.65	2.50	3.05
Total	0.87	1.70	1.95	2.30	3.17

0, heaviest; 4, lightest.

increasing 'heaviness' relative to the standard. The medians of the 20 subjects' median judgements for each test stimulus are given in Table 1.

All the colours were regarded as heavier than the standard, with red the heaviest, yellow the lightest and the other three clustered in between. A Friedman two-way analysis of variance by ranks indicates that the effect of colour was highly significant ($P < 0.001$). On a Wilcoxon matched pairs test, yellow comes out as significantly lighter than all the other colours ($P < 0.05$ or better), and red as significantly heavier than green, orange and yellow.

The average ranks (from 0 as the heaviest to 4 as the lightest) attributed to each colour are shown in Table 2. Though the rank ordering of the different colours was generally consistent across subjects, there was considerable variation in the absolute distance to which the pointer was displaced, some subjects tending to stick close to the mid-point, while others used nearly the full length of the slit (the inter-quartile range for red extended from 1.7–5.7 cm). Men and women gave essentially similar results.

The results for brightness showed no significant effects of any kind.

No plausible explanation has yet been offered for why people should see any equivalence between colour and weight, nor can we offer one. Bullough suggested an explanation in terms of landscape associations and aerial perspective; but he himself considered this argument *ad hoc* and unconvincing. Indirect associations, of the kind 'red=important=heavy', seem more likely. Red is commonly regarded as a particularly striking colour; moreover, in tests of colour preferences, red and blue are generally considered the most pleasant colours, yellow the least pleasant. A correlation between saliency or colour preference and apparent weight, however, if it exists, has little explanatory power. The reasons for colour preferences are themselves unclear. Whatever the explanation, the consistency with which people make such peculiar 'synaesthetic' judgements about the affective value of colours is remarkable.

Male sterility induced in barley by photoperiod

THE continuous exposure of barley plants to short photoperiods leads to marked increases in the numbers of primordia and grains per ear^{1–4}. But little is known of the effects of brief exposures to short days and here we describe the distinctive effects of such

treatments given at different stages of ear development, on the fertility of the florets of ears of barley.

Seeds of barley (cultivar 'Proctor') were sown four per 4 inch pot containing John Innes compost No. 2, in a greenhouse in March 1973. After 10 d the resultant seedlings were thinned to give a uniform stand of two plants per pot. Except when given the short day treatments, plants were grown in a 16 h photoperiod comprising 8 h of daylight (0900h–1700h) in the greenhouse and 8 h of incandescent light (1700h–0100h) of an intensity of approximately 400 lx at pot height, in adjacent photoperiod chambers. The experimental layout consisted of eight randomised blocks, with each block taking up a single trolley. The trolley positions within both the greenhouse and photoperiod chambers were randomised daily to minimise block differences.

Immediately after the appearance of double ridges on the main shoot apex, the first of four transferences of plants into short days was carried out, 21 d after sowing (treatment A). The other groups of plants were transferred 35 d (treatment B), 42 d (treatment C) and 56 d (treatment D) after sowing. These plants received a photoperiod of 10 h for 14 d, this consisting of 8 h of daylight in the greenhouse (0900h–1700h) and 2 h of incandescent light (1700h–1900h) in photoperiod chambers situated next to the ones accommodating the plants receiving long days.

During the treatment period, those plants receiving the short photoperiods were removed from the different blocks and carried on a single trolley. After the 14 d treatment period, the pots were returned to their original positions, within blocks, on the various trolleys. At the beginning of each treatment, eight pots were selected at random and the plants dissected to determine the stage of development of the main shoot apex. These stages were the double ridge stage (treatment A), stamen initial stage (treatment B), awn initial stage (treatment C) and the final stage of ear differentiation with the awns longer than the spike (treatment D). The progress of ear development in the main shoot of the treated and control plants was determined by examining the apices of 16 plants sampled at weekly

intervals; the apices were fixed in 1:3 acetic alcohol and kept for subsequent examination. Sixteen pots were kept in long days throughout to serve as controls. The treated and control plants reached ripe-harvest maturity in a 2 week period at the end of July. At maturity, the numbers of ears per plant and of fertile and infertile florets for the individual ears were recorded. In the latter context the number of florets was counted from the first floret above the collar. Floret fertility is calculated as grain number divided by floret number and expressed as a percentage.

The short day treatments did not affect ear numbers per plant (Table 1). When imposed during the later stages of ear development, however, they markedly reduced the numbers of grains set per plant (Treatments C, D, Fig. 1a). The reductions were due to a significant depression of floret fertility rather than to any decrease in the numbers of florets produced per plant (Figs. 1b and c).

The reductions in floret fertility shown by treatments C and D were not distributed evenly between the various ears of the plant. Thus, when short days were imposed from the awn-initial stage (treatment C) the ear of the main shoot became almost wholly sterile, the ears in the axils of leaves 1 and 2 were unaffected and the ear in the axil of leaf 3 showed a small increase in fertility. In contrast, treatment D, which started when the awns of the main shoot apex were longer than the spike, caused almost total sterility of the axillary ears with the main shoot ear being hardly affected (Fig. 2).

Cytogenetic studies of main shoot ears of plants which had received treatment C showed pollen development to be abnormal. Thus 1 week before anthesis the young pollen grains were aggregated together and showed thick walls and irregularities in both size and shape; there was also a high frequency of nuclear aberrations with the occurrence of many bi- and multinucleates and micronuclei. At ear emergence, the anther contents had completely aborted and anthers were small and shrivelled. It seems likely, therefore, that male sterility was a major cause of floret sterility in the main shoot ears given treatment C.

Dissections of ovaries did not bring to light any obvious effect of treatment C on the development of the embryo sac. But this could not be regarded as conclusive proof that female development was unaffected as dissecting the ovary often led to fragmentation of the embryo sac into its constituent cells so as to make accurate comparisons difficult. Further evidence was therefore obtained from another experiment in which the florets on one side of the main shoot ears of plants which had received treatment C were cross pollinated with pollen from plants grown throughout in long days. The florets on the other side of these ears were not cross pollinated, so that any grain which set would be the result of self pollination. Grain numbers on the self pollinated side of the ear were very low, whilst those

Fig. 1 The effects of a 2-week exposure to short days imposed at the double ridge stage, A; stamen-initial stage, B; awn-initial stage, C; and the later stages of awn differentiation, D on a, grain number per plant, b, floret number per plant and c, % floret fertility per plant. (Bar, least significant difference at $P < 0.05$.)

Table 1 Effect of photoperiod at different stages of ear development

Character	Control	A	B	C	D	L.S.D. $P < 0.05$
Ear number per plant	3.87	3.72	3.44	3.87	3.59	0.35
Total number of grains per plant	62.87	60.25	58.91	51.78	27.63	5.63
Total number of florets per plant	97.62	95.69	92.41	101.37	91.84	8.07
% fertile florets per plant	65	63	64	51	30	5
% floret fertility, main shoot	90	76	70	15	67	9
% floret fertility, leaf 1 tiller	59	67	30	53	14	16
% floret fertility, leaf 2 tiller	68	63	70	66	5	8
% floret fertility, leaf 3 tiller	55	61	77	68	6	9

A 2-week exposure to short days (10 h) was imposed at the double ridge stage, A; stamen-initial stage, B; awn-initial stage, C; and the later stages of awn differentiation, D.

Fig. 2 The effects of a 2-week exposure to short days imposed at the awn-initial stage C (●—●) and the later stages of awn differentiation D (○—○) on the fertility of the florets of main shoot ears M, and the leaf 1, 2 and 3 tiller ears (L1, L2, L3). Fertility in all ears is calculated as (Grain No.)/(Floret No.) \times 100 and is plotted as a percentage of the control value.

on the cross pollinated side were considerably higher (Table 2). It seems, therefore, that the short day treatment had not affected the development of the embryo sac and that its effect on floret fertility was exerted by the induction of male sterility.

It is intriguing to consider why main shoot ears were affected by treatment C but not treatment D. It seems unlikely that the plants became unreceptive to the short day stimuli during treatment D, as the fertility of the florets of the lateral ears was markedly reduced by such treatment. It would seem more likely that pollen development is sensitive to short days only at certain stages and that in the main shoot ears these coincided with the exposure to short days in treatment C but not treatment D. The actual stages of pollen development covered by treatment C range from mitosis of the pollen mother cells at the start of treatment to the first prophase of meiosis at the end of treatment. As male and female meiosis have been shown to be synchronous in barley⁵, the embryo sac mother cell would have been at a comparable stage at the end of the treatment period.

Although any stage in the span of development covered by treatment C could be the critical process which is sensitive to short days, it may prove to be the stage of premeiotic interphase which is disrupted. This phase, in which the mitotic pollen mother cells are synchronised before entering meiosis, only occurs in male gamete formation, and it has been shown to be susceptible to changes in other environmental factors which induce varying degrees of floret sterility⁶⁻⁸.

No dissections of lateral ears were carried out but it was observed that the general development of these was later than that of main shoot ears, and it is likely, therefore, that the development of pollen in their florets lagged behind that in the main shoot ears. If this occurred, then the reduction in floret fertility in the lateral ears induced by treatment D, but not treatment C, would be consistent with the hypothesis that there is a stage during which pollen development is sensitive to short days and that this is the same for all ears.

The drastic reduction in floret fertility caused by exposure to short days is a new phenomenon. The mechanism of this effect is not clear, but phytohormones may be involved. There is evidence that levels of phytohormones in plant tissues change in

response to day length^{9,10}, and that such substances can affect floret fertility. Thus application of ethrel decreases floret fertility in both barley¹¹ and wheat¹², whereas gibberellins increase fertility in male sterile lines of tomato¹³ and barley¹⁴.

The results described here imply that the use of physiologically induced male sterility may well be feasible in the controlled hybridisation of barley varieties, particularly where a rapid assessment of heterotic combinations is needed in the choosing of parents for the production of hybrid barley varieties.

We wish to thank Dr M. D. Bennett of the Plant Breeding Institute, Cambridge, for his assistance in the cytogenetic studies reported in this letter.

Fluidisation as a feeding mechanism in beach flies

WE have seen groups of small (4-5 mm long) grey flies belonging to the species *Lipochaeta slossonae* Coquillett, 1896, standing, shaking and apparently feeding, or flying for short distances on stretches of wet sandy beach in La Jolla, California and San Felipe, Mexico. When undisturbed, they walked sideways or stood and shook their bodies, diagonally forward and downward, and backwards and upwards, at an estimated frequency of 5 s⁻¹. We guessed that they were fluidising the wet sand under their feet and thereby loosening some of the interstitial microflora which could then be sucked up as a kind of soup. This was confirmed by laboratory examination of the guts of several specimens, which contained the remains of large numbers of cells of dinoflagellates and diatoms. (The species of dinoflagellates were unfortunately unidentifiable since there were no cell wall remains, but they probably belonged to the genus *Amphidinium*, which comprises some of the commonest unarmoured interstitial dinoflagellates on this beach. The diatom species, however, could be readily identified by their silica walls. There were at least 10 genera, all typical of the marine interstitial community, including various species of *Navicula*, *Nitzschia*, *Pinnularia* and *Amphora*.)

The genus *Lipochaeta* has only one known species, *L. slossonae*: it is a poorly known fly, adults having been hitherto recorded only from Florida, Texas and from southern and central California^{1,2}. Its larvae and pupae are apparently still undescribed (B. A. Foote, personal communication). Very little is known about its biology

Table 2 Effects of cross-pollination with pollen from plants grown in long days throughout

	P: Cross-pollinated	Q: Self-pollinated	L.S.D. $P < 0.01$
Grain No. (one side of ear)	4.89	0.86	2.28
% floret fertility (one side of ear)	41.82%	7.26%	19.24%

The recipient plants were exposed to 2 weeks of short days at the awn-initial stage. The florets on one side of the ear (P) were cross pollinated using pollen taken from plants kept entirely in long days, while those on the other side (Q) were self-pollinated. Figures are the mean of 25 ears.

Fig. 1 Stereoscan electron micrograph taken on Cambridge S-4 SEM of portion of surface of clypeus, showing recurved hairs in bundles of 12-15. (Scale bar = 10 μ m.)

apart from the fact that adults are commonly found on moist sand of ocean beaches. They are not strong fliers, but they seem to be more wary and less easily caught than the kelp flies present in the same habitat.

The head, somewhat resembling that of a fish, is flattened dorso-ventrally, with an almost flat ventral clypeus covered by small recurved hairs grouped in bundles of 12-15 (Fig. 1). This is probably an adaptation for preventing wetting of the head while the fly is feeding. The antennae, which are extremely small and lack an arista, are inserted in pits spaced far apart (Fig. 2). The mouth parts are of the normal dipteran type except for the labella, which are modified to form a filtering apparatus: it has thickened ridges approximately 8 μ m apart and 10 μ m long (Fig. 3), leaving pores of a size suitable for the admission of small diatoms and other algae while excluding sand grains. Further feeding adaptations of these otherwise bristle-less flies² may be the long, stout spines along their legs and the strong apical tarsal claws which enable them to stand on wet sand without wetting the velvety hair cover of their legs and body.

Fig. 2 Lateral view of head of *Lipochaeta slossonae*, showing flattened ventral clypeus, eye, and small antenna in pit. (Scale bar = 500 μ m; stereoscan electron micrograph taken on Cambridge S-4 SEM.)

Many adult ephydriids, like their larvae, are known to feed on microscopic algae³. Analyses of algae found in the guts of a considerable number of species are presented by Deonier⁴, who also reviewed several earlier references on the feeding habits and diets of adult ephydriid flies. A significant observation on the feeding behaviour of adult *Scatella subguttata* (Ephydriidae) is that of Brauns⁵, who refers to pressure by the anterior, boat-shaped portion of the proboscis as being somehow involved in the "licking" of food organisms from sand grains. But the phenomenon of sand fluidisation, which we observed in the feeding behaviour of *Lipochaeta*, does not seem to have been reported elsewhere. Deonier⁶ merely reported that the adults of certain species of *Hydrellia* (Ephydriidae) "exhibit peculiar behaviour while feeding, e.g., *H. biloxiae* rhythmically pushes its body up and down", without offering further explanation of this unusual behaviour. Ocypodid crabs are known to feed on interstitial microflora by rolling wet sand into pellets with their maxillipeds and then sucking out the suspension of fine organic detritus, including the microalgae⁷. Apparently some flies can exploit the same dietary niche.

Fig. 3 Ventral view of portion of proboscis showing 'pores' on labella and small internal teeth. (Scale bar = 50 μ m; stereoscan electron micrograph taken on Cambridge S-4 SEM.)

We thank Dr W. W. Wirth, USDA, c/o US National Museum, Washington, DC, for identifying the fly species, Ellen Flentye for technical assistance with the scanning electron microscope and the Foundation for Ocean Research for financial support to L.C.

New Books in Geosciences

THE DEVELOPMENT OF THE CHLORINITY/SALINITY CONCEPT IN OCEANOGRAPHY

by W. J. WALLACE, California State University, San Diego.
Elsevier Oceanography Series, Vol. 7
1974, 240 pages, 49 tables, 322 refs.,
US \$ 17.70/Dfl. 46.00
ISBN 0-444-41118-6

CONTENTS: The views of antiquity on salt and sea water: Water analysis prior to Boyle; Solution analysis prior to Boyle; The late seventeenth century. Robert Boyle. The beginnings of the systematic study of the sea: Halley and Marsilli. Foundations of systematic mineral and sea water analyses: Giannetti; Lavoisier; Bergman. Sea water analysis and the precipitation method: Murray; Marcet; Usiglio. Constant proportionality of constituents: Gay-Lussac; Maury. The coefficient: Roux; H. M. S. Challenger; Dittmar. The equation. Conclusions. Appendices.

HANDBOOK OF SOIL MECHANICS

Volume 1: Soil Physics

by A. KEZDI, Technical University of Budapest, Hungary.
1974, 294 pages,
US \$ 28.50/Dfl. 74.00
ISBN 0-444-99890-x

This is a completely revised and updated English edition of a book which has already appeared in Hungarian (3rd ed.) and German (2nd ed.). It consists of four volumes, dealing with the physical properties of soils; with applications in the field of foundation engineering, earth works and road construction; soil testing; practical applications, case histories, respectively.

THE STRUCTURE OF THE EARTH'S CRUST Based on Seismic Data

edited by S. MUELLER, Zurich.
Developments in Geotectonics, Vol. 8
1974, 398 pages,
US \$ 38.40/Dfl. 100.00
ISBN 0-444-41191-7

Contains 33 papers presented at an International Upper Mantle Project (IUMP) Symposium held on July 30-31, 1971, prior to the 15th General Assembly of the International Union of Geodesy and Geophysics in Moscow.

GEOMATHEMATICS Mathematical background and geo-science applications

by F. P. AGTERBERG, Geological Survey of Canada, Ottawa.
Developments in Geomathematics, Vol. 1
1974, 612 pages,
US \$ 51.90/Dfl. 135.00
ISBN 0-444-41091-0

CONTENTS: Mathematical models in geology. Review of calculus. Elementary matrices. Geometry. Factor analysis. Probability and statistics. Frequency distributions and functions of independent random variables. Statistical dependence; multiple regression. Trend analysis. Stationary random variables and kriging. Harmonic analysis and power spectra. Powers of matrices and Markov chains. Multivariate stochastic process-models with applications to the petrology of basalts. Calculation of preferred orientations from vectorial data. Spatial variability of multivariate systems.

THEORY OF ERRORS AND GENERALIZED MATRIX INVERSES

by A. BJERHAMMAR, Royal Institute of Technology, Stockholm, Sweden.
1973, 432 pages, 87 tables, 62 illus.,
US \$ 48.00 / Dfl. 125.00
ISBN 0-444-40981-5

CONTENTS: Stochastic models. Hypothesis testing. Samples. The normal distribution. Student's distribution (computer approach). Fisher's distribution (computer approach). The method of least squares. Matrix approach. The central estimation theorem. The method of least squares (adjustment by element of traverses. Adjustment of traverse nets. Triangulation adjustment with analysis of variances. Condition adjustment. Condition adjustment. Combined adjustment. Adjustment of traverses. Advanced analysis of distributions. Variance analysis for relative orientation. Condition adjustment with unknowns. Correlated observations. The optimum network. Advanced estimation. The best linear unbiased estimate. Filtering and prediction. Non-stochastic methods. Numerical methods. Error norms. Geometrical approach to least squares. *Appendix:* General definitions and computational rules for matrix calculations.

NON-AGRICULTURAL APPLICATIONS OF SOIL SURVEYS

edited by R. W. SIMONSON, Soil Survey, Soil Conservation Service, U.S. Department of Agriculture, Washington, D.C., U.S.A.
Developments in Soil Science, Vol. 4
1973, 179 pages,
US \$ 17.30/Dfl. 45.00
ISBN 0-444-41199-2

This volume deals with five major topics of non-agricultural applications of soil surveys. How information about the nature and distribution of soils in suburban areas has been or can be used to avoid problems of various kinds is indicated. Construction using earthy materials in foundations, highways and dikes is discussed. The disposal of liquid and solid wastes, especially from cities and suburbs, but also of farm wastes, is an additional topic. Applications of archaeology and geology research, and the making and interpretation of a soil survey of a mountainous national park are also dealt with.

VEGETATION AND VEGETATIONAL HISTORY OF NORTHERN LATIN AMERICA

edited by A. GRAHAM, Kent State University, Ohio, U.S.A.
1973, 406 pages, 43 tables, 91 illus.,
US \$ 46.15 / Dfl. 120.00
ISBN 0-444-41056-2

CONTENTS: The Vegetation of the Antilles. A Paleoclimatic Interpretation of the Eocene Floras of Southeastern North America. Geographical Relationships of the Flora of Mexican Dry Regions. Ecology of the Vegetation of Veracruz. The Phytogeography and Vegetation of Chiapas (Mexico). The Vegetation of Panama: a Review. Phytogeographic History of the Isthmus of Panama during the Past 12,000 Years (A History of Vegetation, Climate, and Sea-level Change). History of the Arborescent Temperate Element in the Northern Latin American Biota. Literature on Vegetational History in Latin America.

ACTINOMETRY, ATMOSPHERIC OPTICS, OZONOMETRY

Edited by **G. P. Gushchin**, *Voeikov Main Geophysical Observatory, Leningrad*.

This volume comprises papers dealing with methods and results of measuring radiation balance components, spectral transmission of the atmosphere, UV radiation, range of visibility, and the overall abundance of atmospheric ozone. (*Translated from the Russian*). June 1974 206 pages £8.45

Published by Israel Program for Scientific Translations Ltd., and distributed by John Wiley and Sons Ltd.

ATMOSPHERIC RADIATION STUDIES

Edited by **K. Ya. Kondrat'ev**, *Voeikov Main Geophysical Observatory, Leningrad*.

The papers in this collection were written by staff members of the Department of Radiation Studies of the Main Geophysical Observatory and several allied institutions, and deal with radiative processes in the atmosphere. Results are presented of studies of satellite meteorology, and the transport of short- and long-wave radiation in the atmosphere. (*Translated from the Russian*). June 1974 224 pages £8.45

Published by Israel Program for Scientific Translations Ltd., and distributed by John Wiley and Sons Ltd.

RESEARCH ADVANCES IN ALCOHOL AND DRUG PROBLEMS, VOLUME 1

Edited by **Robert J. Gibbins**, *Yedy Israel*, **Harold Kalant**, **Robert E. Popham**, **Wolfgang Schmidt** and **Reginald G. Smart**, all of the *University of Toronto and Addiction Research Foundation, Toronto*.

The first volume in a series that will critically review research from all disciplines that contributes to our understanding of drug and alcohol problems. Papers will deal with selected topics in which enough recent progress has been made to warrant a review or in which debate of confusion require analysis and clarification.

LESIONS IN THE UPPER RESPIRATORY TRACT IN BLOOD DYSCRASIAS

By **L. V. Skurkovich**, *Meditsina Publishing House, Moscow*.

This monograph deals with the diagnosis, clinical aspects, and treatment of upper respiratory tract lesions in cases of leukemia, erythremia, Hodgkin's disease, hypo- and aplastic anemia, agranulo-cytosis, and infectious mononucleosis. The book summarizes the experience of the author, acquired during many years of comprehensive work at hematological departments. (*Translated from the Russian*).

THE SEA: Volume 5: Marine Chemistry (The Sea)

Edited by **Edward D. Goldberg**, of *Scripps Institution of Oceanography*.

Based on the work of Lars Gunnar Sillén whose quest to understand the chemical reactions that determine the composition of seawaters laid a new foundation for investigation in marine chemistry. Provides both an assessment of knowledge relative to the problems proposed by Sillén and studies of unexplored realms of marine chemistry.

BIOLOGICAL CLOCKS IN MARINE ORGANISMS: The Control of Physiological and Behavioral Tidal Rhythms

By **John D. Palmer**, *New York University*.

A survey of bioclock-controlled tidal rhythms—those organismic rhythms that persist over periods of approximately 12.4 h in constant conditions in the laboratory. First provides familiarity with the basic subject matter, then describes experiments with tidal rhythms and the properties derived from these laboratory manipulations. Finally, uses some of these properties—and those of circadian rhythms—to draw a rough sketch of the clockworks that underly persistent rhythms.

NUTRITION AND FETAL DEVELOPMENT

Edited by **Myron Winick**, *Columbia University College of Physicians and Surgeons*.

Nine original articles focus on the most recent research conducted on prenatal malnutrition in both human and animal populations. Considers how maternal malnutrition affects foetal brain development and subsequent behaviour in animals, tells how in humans, maternal undernutrition affects the cellular growth of the placenta and reproduces biochemical signs of malnutrition in foetal serum and white cells. Given data show that many of these changes can be reversed by supplementing the diet of pregnant women. (*Current concepts in Nutrition, Volume 2*).

THE THEORY OF RATE PROCESSES IN BIOLOGY AND MEDICINE

By **Frank H. Johnson**, *Princeton University*, **Henry Eyring**, *University of Utah*, and **Betsy Jones Stover**, *Universities of North Carolina and Utah*.

Outlines the conceptual basis of modern reaction-rate theory—the theory of absolute reaction rates—and applies the net results of this theory to representative rate processes in biology and medicine in an effort to achieve a better understanding of the phenomena involved.

Proof of natural selection

The Triumph of the Darwinian Method. By M. T. Ghiselin. Pp. 287. (University of California: Berkeley, Los Angeles and London, May 1973.) £1.50 paper.

IN 1909, the fiftieth anniversary of the publication of *On the Origin of Species* and the centenary of Charles Darwin's birth, two large volumes of essays on Darwin's work appeared. *Darwin and Modern Science*, edited by A. C. Seward (Cambridge University Press) and *Fifty Years of Darwinism* (Holt, New York) contained essays from many prominent scientists. Two similar volumes, *A Century of Darwin*, edited by S. A. Barnett (Heinemann, London) and *Darwin's Biological Work*, edited by P. R. Bell (Cambridge University Press) appeared for the centenary of the *Origin* in 1959. Taken together, these four volumes represented until now the most comprehensive evaluation of Darwin's scientific interests and their later influence. The problem is that each contributor to these books considered only one aspect of Darwin's thought. Quite often, contributors disagreed vigorously among themselves about Darwin's methods and significance. The result was a very disjointed appreciation of Darwin's work.

Now Michael Ghiselin has written a much needed and very different kind of book. He read Darwin carefully with the aim of elucidating the unity of conception in his major writings. Dividing Darwin's work into the themes of natural history, geology, zoology, evolution, botany, and psychology, Ghiselin convincingly demonstrates that Darwin approached each with the same general methodology. He also shows clearly how all of Darwin's diverse biological investigations, after he turned from geology, were related to his conception of evolution by natural selection. Thus the monographs on barnacles, the books on worms, climbing plants, and psychology, are seen as parts of a single conception. Ghiselin's argument, though stretched thin in some places, is important and compelling. Indeed, the book might best be titled "The Unity of Darwin's Thought".

In other ways, Ghiselin's book is less successful. His title is drawn from his answer to the question: why did Darwin attain such a remarkable success? Why did he, and not others,

write the classic works in evolutionary biology? After discounting intellect, zeal, labour, and theft from predecessors as the crucial factors, Ghiselin answers: "Darwin's success may readily be explained by a very simple hypothesis which seems not to have occurred to his critics: he thought. He reasoned systematically, imaginatively, and rigorously, and he criticized his own ideas" (page 232). In other words, the key to Darwin's accomplishments was that he "applied, rigorously and consistently, the modern, hypothetico-deductive scientific method" (page 4).

This thesis is deficient. A great number of intelligent biologists have used the same general method and have not enjoyed Darwin's success. In the final pages Ghiselin tempers his thesis by admitting that "Darwin's strength of character, his self esteem, and his ambition are in no small measure responsible for his success" (page 242); also implicated were Darwin's courage, his "remarkable talent for judging the appropriate", his ideals, and his value system. Another perhaps important reason why Darwin had greater success than his competitors is that he had the immense advantage of nearly twenty years of reflection and gathering of evidence when it came to the application of the central ideas of the *Origin* to diverse areas of biology. Even then he had no monopoly on the idea of natural selection. For example, H. W. Bates, A. R. Wallace, and Fritz Müller developed mimicry theory, which has been a mainstay of the theory of natural selection from the early 1860s to the present. Clearly the keys to Darwin's success are more complicated than Ghiselin suggests in his title and major thesis.

The picture Ghiselin paints is this: Darwin, exemplar of scientific virtue, almost singlehandedly develops the theory of evolution by natural selection and applies it to many areas of biology. Because of stupidity, belief in design or final causes, religious prejudices, and general lack of appreciation of his methods and results, Darwin's contemporaries and successors constantly misinterpret and attack the theory of natural selection. "To some extent", admits Ghiselin, "these contrary views were justified by the difficulties of the scientific problem"

(page 7). Only with R. A. Fisher's *The Genetical Theory of Natural Selection* (Oxford University Press) in 1930 is the great part of this misinterpretation cleared away, leading for the first time to a proper appreciation of Darwin's ideas. Ghiselin, himself, is finishing the mop-up of Darwin's critics begun by Fisher in 1930, and continued in his 1954 essay, "Retrospect of the Criticisms of the Theory of Natural Selection" in *Evolution as a process*, edited by Huxley, Hardy and Ford (Allen and Unwin, London). But this picture of the hiatus of proper understanding in the time between Darwin and Fisher is seriously misleading. Who can believe that all the great biologists of the late nineteenth and early twentieth centuries were too limited to understand Darwin's theories? August Weismann, Hugo de Vries, William Bateson, Wilhelm Johannsen, Jacques Loeb, Thomas Hunt Morgan, even Francis Darwin, to mention only a few: how could they have failed to appreciate Darwin's theory of natural selection when any smart college student can succeed today? Something is wrong with Ghiselin's analysis of Darwin and his critics.

Here is the problem. Ghiselin believes that the theory of natural selection is Darwin's most important contribution to knowledge. I agree. Ghiselin believes further that Darwin presented adequate verification for natural selection. I disagree, along with Darwin's successors. Noting that Darwin believed he could not see natural selection in action because of its slowness, Ghiselin refutes Darwin's critics of the nineteenth century with this argument:

"The problem is no longer with us, since the production of new species in the laboratory, by processes known to occur in nature, is a mere chore. However, direct observations on the process of speciation were by no means necessary: Darwin answered his critics by maintaining that he could verify his theory indirectly by its implication of a large number of readily ascertained facts. Actually, the attack (upon natural selection) was wholly unfounded and most unphilosophical" (page 62).

To this Ghiselin adds that "we have no 'direct' evidence for the truth of any scientific theory", implying that Darwin's critics needed no more evidence than they got, although Ghiselin himself invokes modern laboratory experiments.

The only examples of natural selection in action Darwin provided in the *Origin* were, as he clearly stated, "imaginary" (page 90 in facsimile of first edition, Harvard University Press, 1964). As even Ghiselin admits, Darwin's theory of pangenesis and his ideas about the origin and maintenance of heritable variability in natural populations were unconvincing; yet natural selection depended upon an exact understanding of this variability. There was ample room for criticism of natural selection. One need only read Thomas Hunt Morgan's 1903 critique of Darwin, *Evolution and Adaptation* (Macmillan, New York) to see why an intelligent biologist could read Darwin carefully and still reject crucial aspects of his idea of natural selection. By reading twentieth century Darwinism back into Darwin, torical proportion his book requires.

Despite these criticisms, this book is the best available analysis of Darwin's works, and it is sure to stimulate substantial further research. In addition, the book contains a wealth of other ideas. Ghiselin analyses aspects of scientific method, philosophy, religion, and history; he even has a comparison of human history with geology and palaeontology. His arguments are consistently bold, clear and provocative. Although readers will surely wish to challenge many of these arguments, they will find this carefully researched book a refreshing and stimulating change from the usual fare of Darwin literature.

WILLIAM B. PROVINCE

Collisions in gases

Partially Ionised Gases. By M. Mitchner and Charles H. Kurger jun. Pp. 518. (Wiley Series in Plasma Physics.) (New York and London: Wiley-Interscience, November, 1973.) £12.50.

THIS book is concerned with the theory of collision-dominated plasmas and its application to practical engineering problems, particularly magnetohydrodynamic (MHD) energy conversion. It can be used as a text for graduate level courses of different emphases, by choosing appropriate parts of the nine chapters. The authors have taught the material in this way and make suggestions based on their experience in the introductory chapter.

Chapter 2 begins the book proper, introducing the physical concepts needed to understand collisional and radiative processes. More than twenty graphs for selected collision cross-sections as a function of energy are given at the end of the chapter, so that the order of magnitude of many cross sections not included can be estimated from this collection.

Chapter 3 deals in more detail with plasmas at rest and has a section on diagnostics, which unfortunately includes the erroneous statement that ion temperatures can be deduced from probe curves. The references quoted would correct this. The magnetohydrodynamic equations of motion are derived in chapter 4, after particle motion in combined static E and B fields has been discussed. This leads to a treatment of MHD power generation and other phenomena in flowing magnetised plasmas.

Collision theory as applied to elastic collisions in plasmas is described in chapter 5, where Coulomb scattering and three-body recombination appear. Radiation from plasmas is treated instructively on a semi-classical basis in chapter 6. A more formal treatment of elastic collisions on the basis of a fuller kinetic theory appears in chapter 7. The Cartesian-tensor expansion of the Boltzmann equation is introduced here and applied in chapter 8 to the calculation of transport coefficients for plasmas of all degrees of ionisation.

Inelastic collisions, which determine the degree of ionisation, are considered in chapter 9 on ionisational non-equilibrium. Departures from the Saha equation due to escape of radiation from steady-state plasmas are discussed, as are non-Maxwellian distributions and flowing plasmas.

The material is clearly presented; obviously this textbook has grown out of genuine efforts to teach. A fine selection of numerical examples is provided with each topic, and a multitude of references after each chapter. This makes the book useful as a guide to the original work. Beginners in the field of high temperature gas dynamics would be helped by the discussion of techniques for carrying out useful approximate calculations, and by the data presented in graphical and tabular form throughout the book.

The book is well printed and bound—though my copy contains some optically thin pages—and the diagrams are excellent.

P. F. LITTLE

Reproductive handbook

Female Reproductive System. Edited by R. O. Greep. Part 1: pp. 658; part 2 pp. 375. (Handbook of Physiology: A Critical Comprehensive Presentation of Physiological Knowledge and Concepts. Section 7: Endocrinology: Vol 2.) (American Physiological Society: Washington DC; Distributed by Williams and Wilkins, Baltimore, 1973.) Part 1; \$44.50; part 2; \$25.00.

THIS latest volume of the American Physiological Society's "Handbook of Physiology" maintains the very high standard of its predecessors. Roy Greep has obtained a galaxy of stars to write the 50 chapters on central nervous

system-pituitary-ovarian interrelationships, effects of hormones on sexual behaviour, ovary, female reproductive tract, pregnancy, immunoendocrinology, and fertility control. Greep's approach might appear somewhat parochial in that only four of the chapters have been written by authors not attached to North American laboratories, but it is a pity that his modesty prevented the addition of a chapter under his own authorship.

The various sections made very stimulating reading, though the chapters on, for example, the biosynthesis of the ovarian steroids inevitably provided heavier reading than did other chapters. In general, although each chapter overflows with pertinent information, the provision of facts has not been permitted to obliterate the fundamental concepts that are discussed. As an excellent example of this I would cite Joan Hoffmann's chapter on "The Influence of Photoperiods on Reproductive Function in Female Mammals" in which she lucidly introduces her subject and then continues, to produce a clear diagrammatic summary of the possible interplay in the rat of photoperiodic inputs, hormone levels, and neural thresholds to permit, or otherwise, the pre-ovulatory surge of luteinising hormone. Richard Michael's chapter on "The Effects of Hormones on Sexual Behavior in Female Cat and Rhesus Monkey" is equally entertaining, though it was noticeable that one quarter of the 205 references came from Michael's own publications.

The high standard of production of this volume is reflected in the excellent reproduction of all figures. This standard of illustration is particularly of note in the chapter by S. R. M. Reynolds on "Blood and Lymph Vascular Systems of the Ovary" and the chapter by Arthur Hertig and Barbara Barton on "Fine Structure of Mammalian Oocytes and Ova".

I would quibble, though, with the use of numbers in the text instead of authors' names to indicate references. References are, however, now quoted with full titles, which is an improvement since the handbook first appeared in 1959. Inevitably, reference could in general only be made to works published up to early 1971, and, as a result, some areas of current interest such as those of releasing factors or prostatic glands are not up to date nor given much coverage.

I would, however, recommend unequivocally that anyone working in the field of reproductive physiology should invest in this volume. It certainly fulfils the stated intention of providing a reference 'bible' for predoctoral study, for preliminary orientation in preparation for research, and for preparation of lectures.

BAREND TER HAAR

obituary

I. Lakatos

IMRE LAKATOS, Professor of Logic at the London School of Economics, was born in Hungary in 1922 and died suddenly in London on February 2, 1974. He was a forceful and original thinker, with an equally forceful and original personality. His chief contributions lay in the philosophy and history of mathematics and of the physical sciences. To those who found the combination of philosophy with history a strange one, Lakatos replied (paraphrasing Kant), "Philosophy of science without history of science is empty; history of science without philosophy of science is blind".

Most people think that the history of mathematics, while a legitimate object of curiosity, is not essential to the understanding or philosophical evaluation of mathematics itself. In mathematics, they say, we begin with axioms and definitions, and prove theorems from them. But Lakatos asked how the axioms and definitions came to be proposed, and how the proofs came to be discovered. Answering these questions led him into the territory of mathematical discovery or mathematical heuristics. It is a strange territory, where theorems get proved and then refuted, where the theorem and its proof get elaborated to deal with the refutation, refuted again, and once more elaborated, until in the end something like an axiomatic theory emerges. Lakatos's brilliant 'Proofs and Refutations' (*Br. J. Phil. Sci.*, 1963) is a case study of this process. Its dialogue form is no accident, for according

to Lakatos, mathematical discovery is brought about, essentially, by critical debate. The dialogue sparkles, and comes nearer than any of Lakatos's writings to capturing the unique style of the man.

Working mathematicians who, after all, inhabit these regions may find Lakatos's topography of them familiar. And yet the mathematics student is still confronted with long and complicated 'definitions', which may be the end product of centuries of trial and error, and expected to understand them without knowing their history. All he can do in this situation is memorise the definitions parrot fashion. The implications of Lakatos's work for the teaching of mathematics have yet to be explored.

Philosophers of mathematics have a different reaction to Lakatos's work. They insist that what he describes is only the murky preamble to the placing of mathematical results on a firm, rigorous and certain foundation. They see nothing in it to alter their view, held since Plato, that mathematics is the repository of absolutely certain knowledge. In another important paper, 'Infinite Regress and the Foundations of Mathematics', (*Aristotelian Soc., supplementary volume*, 1962) Lakatos examined the most recent attempts to provide secure foundations for mathematical theories (Frege, Russell and Hilbert). He showed that all these failed, but failed gloriously: their so-called 'foundations of mathematics' actually turned out to be new and exciting mathematical theories (mathematical logic, set theory, and

recursive function theory, respectively).

Much of this carries over to Lakatos's more recent work in the philosophy and history of the physical sciences. Here, of course, Lakatos was heir to the critical philosophy of science of Sir Karl Popper. (Indeed, his philosophy of mathematics is in some respects an extension of Popper's views to mathematics, an extension which Popper himself never made but later welcomed.) Lakatos developed Popper's philosophy of science in two directions. One was the emphasis upon the importance of history for the rational evaluation of scientific theories. He insisted, against the dominant view in this field, that scientific contributions cannot be appraised independently of the historical development which produced them. His second main interest was in whether a critical philosophy of science, which eschews any firm foundations for scientific knowledge, can avoid scepticism and irrationalism. His 'methodology of scientific research programmes' was an attempt to show that it can. In it, he was sharply critical of both the irrationalist tendencies he detected in recent writers (notably Thomas Kuhn) and of some features of Popper's own views.

Like all original work, Lakatos's work raised more questions than it answered. He still had much to teach us about these questions, for he died at the height of his powers. All that remains is to hope that his unpublished work, which is considerable, will appear, and that the students he inspired will continue the 'research programme' which he initiated.

Announcements

Awards

Graham Higman has been awarded the De Morgan Medal and Paul M. Cohn the Senior Berwick Prize of the London Mathematical Society (corrected announcement).

Cecil A. Hoare has been awarded the Manson Medal and Alister Voller the Chalmers Medal of the Royal Society of Tropical Medicine and Hygiene.

Appointments

David Robinson has been appointed Professor of Food Science at the University of Leeds.

R. E. Cotton, B. D. Edwards, J. A. Scott and G. K. Williamson have been awarded Special Professorships at the University of Nottingham.

Erratum

In the article "Aftershocks caused by the Novaya Zemlya explosion on October 27, 1973" by Hans Israelson, Ragnar Slunga and Ola Dahlman (*Nature*, **247**, 450; 1974) the distance scale in Fig. 1 should read 500 km. See also *Nature*, **248**, 712; 1974.

APPOINTMENTS VACANT

DIRECTOR

The Jackson Laboratory invites applications for the position of Director of the Laboratory, which will become open on October 1, 1975. Qualified applicants are invited to submit a curriculum vitae and summary of experience to one of the following:

Dr James D. Ebert, Chairman, Search Committee, Marine Biological Laboratory, Woods Hole, Massachusetts 02543;

Dr James F. Crow, Member, Search Committee, Department of Medical Genetics, University of Wisconsin, Madison, Wisconsin 53706;

Dr Douglas L. Coleman, Secretary, Search Committee, The Jackson Laboratory, Bar Harbor, Maine 04609.

AN EQUAL OPPORTUNITY EMPLOYER. (3)

POSTDOCTORATE FELLOW IN IMMUNOGENETICS

Biochemist/Immunochemist with Ph.D. degree needed to work on the genetics of man's immune response toward limiting doses of naturally inhaled protein antigens (highly purified components of pollens, etc.). Opportunity to join a group which has had 3 years experience in this new research area. Excellent facilities and stimulating environment. Candidate must have a sound background in protein purification and characterisation. Experience in radioimmunoassay and leukocyte culture techniques advantageous. Demonstrated creativity in previous research essential. Send detailed curriculum vitae, list of publications and names of two referees to: Dr David G. Marsh, Johns Hopkins University School of Medicine at Good Samaritan Hospital, 5601 Loch Raven Boulevard, Baltimore, Maryland 21239.

Equal Employment Opportunity Employer M/F. (92)

UNIVERSITY OF READING DEPARTMENT OF CHEMISTRY RESEARCH DEMONSTRATORS

required in inorganic and physical chemistry from October 1, 1974, for three year appointment. Candidates should have a good Honours Degree in Chemistry, or equivalent qualifications. Demonstrators help supervise practical classes and undertake research leading to a higher degree (M.Phil or Ph.D.). Salary in the scale £1,046 x 51 to £1,149 p.a. (Under review). Apply to Professor G. W. A. Fowles, Department of Chemistry, University of Reading, Whiteknights, Reading, from whom further information about research topics can be obtained. (Ref: T 52.) (147)

MEMORIAL UNIVERSITY OF NEWFOUNDLAND FACULTY OF MEDICINE

A new medical school in Canada is expanding its faculty and will make post-doctoral and faculty appointments in the field of Human Biochemical Genetics. Candidates must be prepared to work on human biochemical variation in the context of collaborative population studies though this does not preclude the pursuit of other research interests. Interested individuals should submit applications accompanied by a detailed curriculum vitae to Dr K. B. Roberts, Associate Dean for Basic Medical Sciences, Memorial University of Newfoundland, St John's, Newfoundland, A1C 5S7, CANADA. (152)

**Public Service
Canada**

**Fonction publique
Canada**

THIS COMPETITION IS OPEN TO BOTH MEN AND WOMEN

RESEARCH SCIENTISTS

Salary up to: \$24,262

Department of Environment, St. John's, Newfoundland

The Newfoundland Biological Station requires two scientists for research into the biology and population dynamics of pelagic fishes of the Newfoundland-Labrador area.

DUTIES:

- participating in planning, initiating and implementing field and laboratory studies;
- analyzing data and interpreting results for presentation in report of scientific manuscript form;
- keeping abreast of developments in fisheries research;
- assigning duties to and supervising technical staff.

QUALIFICATIONS:

Include a Doctorate degree, or a lesser degree with related independent research experience equivalent to that required for a Doctorate degree, with experience in an area related to the duties of the position. Good health and physical condition with ability to work at sea. Knowledge of the English language is essential for this position.

APPLICATIONS:

Curriculum vitae or "Application for Employment" form, accompanied by complete university transcripts and the names and address of three referees should be forwarded no later than AUGUST 6, 1974 to

THE MANAGER
NEWFOUNDLAND PERSONNEL OFFICE
DEPARTMENT OF ENVIRONMENT
P.O. BOX 5300
ST. JOHN'S, NEWFOUNDLAND.

Please quote competition number: 74-100-31, 44 () in all correspondence.

Appointments as a result of this competition are subject to the provisions of the Public Service Employment Act. (160)

POST DOCTORAL RESEARCH APPOINTMENT

The Forestry Commission offers a period appointment for 3 years for research work in the Physiology Branch at their Northern Research Station, Roslin, Midlothian.

Subjects

- (a) To investigate the internal and environmental control of root initiation in conifers.
- (b) To develop early-test methods—physiological screening techniques, for testing the characteristics of trees while still at the seedling stage.

Qualifications

Ph.D. in plant physiology or other plant science.

Age

Under 30 years on December 31, 1974.

Salary

Negotiable, within the range for Scientific Officer (£1,435 to £2,329) or for Higher Scientific Officer (£2,221 to £2,854)—depending on qualifications and experience.

Closing date for Applications

Application forms and further details may be obtained from Mr. F. M. Muggridge, Forestry Commission, Priestley Road, Basingstoke, Hants RG24 9NS. Completed application forms should be returned not later than July 31, 1974. (161)

UNIVERSITY OF SOUTHAMPTON DEPARTMENT OF MATHEMATICS SEMICONDUCTOR THEORY

Applications are invited from recent graduates for a RESEARCH STUDENTSHIP and from persons completing postgraduate work (M.Sc. or Ph.D.) for a RESEARCH ASSISTANTSHIP. The work involves the application of quantum mechanics and statistical mechanics to problems of recombination in semiconductors with special reference to device physics (solar cells, light emitting diodes, etc.).

A good honours degree in mathematics, physics, engineering or equivalent is essential.

Please apply as soon as possible giving name of one referee to Academic Registrar, The University of Southampton SO9 5NH. (153)

UNIVERSITY OF MANCHESTER RESEARCH ASSISTANT DEPARTMENT OF CHILD HEALTH

Applications are invited from suitably qualified recent graduates for this post with a multidisciplinary research group concerned with growth and development of the brain. The Research Assistant will help with the management of biochemical, animal behavioural and clinical laboratories for which previous experience is not essential. Opportunities exist to prepare for a higher degree. Salary range p.a. £1,569-£1,791 (£1,758-£1,980 from October 1st.). Further particulars and application forms (returnable by July 15th) from the Registrar, The University, Manchester, M13 9PL. Quote ref: 149/74/N. (169)

PHARMACEUTICAL RESEARCH AND DEVELOPMENT

Our extensive research and development laboratories at Loughborough offer an excellent career opportunity for young graduates interested in contributing to our current research programme into respiratory and cardiovascular diseases.

These posts would particularly suit a recent graduate with a good honours degree or equivalent in pharmacology or pharmacy and the enthusiasm and ability to carve out a successful career in a large, progressive research environment.

An attractive competitive starting salary will be offered and excellent conditions of employment include a full range of fringe benefits and opportunities for movement and advancement throughout our R and D function.

Please write with brief details of qualifications held or expected, and information concerning research activities to date:

A.B. Johnston, Fisons Limited, Pharmaceutical Division, Bakewell Road, Loughborough, Leicestershire.

(70)

UNIVERSITY OF RIYADH MEDICAL SCHOOL SAUDI ARABIA (IN ASSOCIATION WITH THE UNIVERSITY OF LONDON)

Applications are invited from male honours graduates for the following posts in Pre-Clinical Medicine at the University of Riyadh Medical School. The vacancies have arisen as a result of the rapid expansion of the School:

ANATOMY—PROFESSOR/LECTURER/DEMONSTRATOR
BIOCHEMISTRY—ASSISTANT LECTURER/DEMONSTRATOR
PHYSIOLOGY—ASSISTANT PROFESSOR/LECTURER/DEMONSTRATOR

Applicants should have a higher degree and teaching experience.

The University of Riyadh is an independent University established in 1957. In 1968 the University established a Medical School in association with the University of London. The request by the University of Riyadh for assistance in this project is covered by a sponsorship agreement. The University of London advises on the curriculum, the form and conduct of examinations, the physical facilities for teaching, the appointment of academic staff and other matters. From the outset it has been anticipated that this assistance would continue over a period of at least 10 years possibly extending to 15 years. All teaching of medical undergraduates is in the English language.

Salary scales:

PROFESSORS—On range Saudi Ryals 6,200 to SR7,200 per month plus a housing allowance of SR12,000 per annum.

ASSISTANT PROFESSORS—On range SR5,200 to SR6,200 per month plus a housing allowance of SR10,000 per annum.

LECTURES—On range SR4,200 to SR5,200 per month plus a housing allowance of SR8,000 per annum.

DEMONSTRATORS—Salary and housing allowance will be negotiable in accordance with qualifications and experience.

CONSULTANCY POSTS—Additional allowances will be paid for appointees holding consultant posts at the Teaching Hospital.

Note: £1 sterling=Saudi Ryals 8.5.

Appointments are for 1 year or longer; renewable. Secondments would be considered.

Detailed applications (3 copies) including a curriculum vitae and naming three referees should be sent not later than July 26, 1974 to the Inter-University Council for Higher Education Overseas, 90-91 Tottenham Court Road, London W1P 0DT from whom further particulars are available. (150)

THE ROYAL VETERINARY COLLEGE (University of London) Division of Paraclinical Studies DEPARTMENT OF PATHOLOGY LECTURER IN VIROLOGY

Applications are invited from veterinary and science graduates for the newly-created post of Lecturer in Virology which is available from October 1, 1974.

Candidates should have considerable post-graduate experience in animal virology and possess a Ph.D. or equivalent degree. The appointee will be required to participate in teaching virology and virus diseases at the undergraduate and postgraduate levels. Strong research interests are essential; good facilities available, including supply of gnotobiotic animals. Prospective applicants are invited to contact Professor W. Plowright for further information.

Salary scale £2,118 to £4,896 plus London Allowance (under review) at present £162 per annum, plus threshold supplement. Initial salary according to qualifications and experience. Superannuation under F.S.S.U.

Application form and further details available from Assistant Secretary (Personnel) (N). The Royal Veterinary College, Royal College Street, London NW1 0TU. **Closing date for applications** August 19, 1974. (149)

INSTITUTE OF CANCER RESEARCH AND ROYAL MARSDEN HOSPITAL DIVISION OF PHYSICS APPLIED TO MEDICINE

Two vacancies will occur in September for Physicists to work in the diagnostic and therapeutic applications of ionizing radiation to medicine. The department is large and well equipped and covers both X-ray beam work, radioisotope work, diagnostic X-rays, and ultrasound. Candidates need not have worked in the medical field but should have a 1st or 2nd Class Honours Degree. Further particulars can be supplied on request. New entrants will be given a thorough training in all aspects of the work. The Institute is an integral part of the British Postgraduate Medical Federation which is a School of London University. Appointments will be made on M.R.C. Scales Grade 2 £1,830-£3,378+£162 London Weighting, or Grade 1 £3,543-£4,548+£162 L.W. depending on the candidate's qualifications and postgraduate experience in medical physics or a closely related field. Superannuation on F.S.S.U. but suitable candidates from N.H.S. can retain existing pension arrangements. Applications giving full curriculum vitae and names of two referees to the Secretary, 34 Sumner Place, SW7 3NU, quoting ref. 300/G/76. (154)

ASSOCIATION OF CLINICAL PATHOLOGISTS

Medical Microbiology for Non-Medically Qualified Microbiologists February 10-21, 1975.

This non-residential lecture course will be held in London at the Adelphi, 1-11 John Adam Street, W.C.2.

The fee payable is £40.

Applications are invited from graduates in science, who are making, or who intend to make a career in Medical Microbiology.

Further information and application forms may be obtained from: Miss Valerie Matt, Department of Microbiology, QUEEN CHARLOTTE'S MATERNITY HOSPITAL, 339 Goldhawk Road, London W6 0XG. (179)

THE UNIVERSITY OF MANCHESTER RESEARCH TECHNICIAN

required to assist with a laboratory investigation on the genetical and cytological basis of sex ratio distortion due to meiotic drive in the mosquito *Aedes aegypti*, supported for two years from a grant by the Science Research Council to Dr R. J. Wood. This post is suitable for a graduate in a biological subject with experience of genetical theory and techniques. Salary £1,704 rising to £1,758 p.a. after one annual increment. Applications, together with the names of two referees, should be sent as soon as possible to Dr R. J. Wood, Department of Zoology, The University, Manchester M13 9PL. (171)

CHARING CROSS HOSPITAL

Fulham Palace Road, Hammersmith W.6

BIOCHEMIST

DEPARTMENT OF MEDICAL ONCOLOGY

Applications are invited for a graduate biochemist to join a team isolating tumour antigens. It is essential that applicants have an interest in protein chemistry and a working knowledge of current separation techniques. Working under supervision, the successful applicant would be given his own project and therefore some previous research experience would be useful. An opportunity would be given to register for a higher degree.

Salary on scale £1,623 to £2,820, inclusive of London Weighting, according to qualifications and experience, plus threshold payment of £5.22 per month.

Further details available from Dr. G. T. Rogers, 01-748 2050 ext. 2087. Application forms from Miss Matthews, Personnel, ext. 2995. (155)

THE LONDON HOSPITAL (WHITECHAPEL)

GRADUATE RESEARCH ASSISTANT OR QUALIFIED TECHNICIAN

Required in the Professorial Gastro-Enterological Research Unit. The work will be concerned with radio-immuno-assay and experience in this technique is desirable.

Applications to R. C. Taylor, Assistant Secretary, The London Hospital (Whitechapel), Whitechapel, London E1 1BB. Tel: 01-247 5454 Extn. 388. (167)

COMMONWEALTH AGRICULTURAL BUREAU

Vacancy for

SCIENTIFIC INFORMATION OFFICER

at the

COMMONWEALTH BUREAU OF SOILS

ROTHAMSTED EXPERIMENTAL STATION
HARPENDEN, HERTFORDSHIRE

Duties: Preparing abstracts for the abstracting journal "Soils and Fertilizers", which covers world scientific literature on soils and soil-plant relationships, and dealing with scientific enquiries within these fields.

Qualifications: A degree in soil science, agricultural science or sciences basic to these. Ability to write good and concise English essential. The successful candidate may be required to learn a foreign language. *Experience or training in information work, including subject indexing, would be an advantage.

Salary: In scale £1,435 to £2,592 (bar), £2,798 to £3,478 (bar), £3,756 to £4,004, plus a compensatory allowance (taxable but not superannuable) of 41% to offset personal contribution to F.S.S.U. Starting salary according to qualifications, experience and age.

Application forms and full particulars from the Secretary, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Slough SL2 3BN.

Closing date for applications: July 29, 1974. (184)

THE QUEEN'S UNIVERSITY OF BELFAST

Lectureship in Geology

Applications are invited for a lectureship in the Department of Geology in the general field of Palaeontology, preferably in Micro-palaeontology. The post is tenable from October 1, 1974 or such other date as may be arranged. Initial placing, which will depend on experience and qualifications will be made at one of the first three points on the scale for lecturers: £2,118, £2,241, £2,412 rising to £4,896 with contributory pension rights under the F.S.S.U. The appointment will be subject to a period of probation of up to three years in duration. Applications should be received by August 10, 1974. Further particulars may be obtained from The Personnel Officer, The Queen's University of Belfast BT7 1NN, Northern Ireland. (Please quote Ref. 74/N.) (168)

Research & Development with Roussel

PHARMACOLOGIST

IMMUNOPHARMACOLOGY

A Pharmacologist with an interest in immunopharmacology is required to join a team working in the field of allergic diseases. The position would suit a recent graduate or equivalent, preferably with 1 to 2 years relevant experience, who is looking for the opportunity to join a progressive and expanding Company.

Roussel Laboratories Ltd. is part of a large, international group researching, developing, manufacturing and marketing a wide range of pharmaceutical and allied products.

Conditions of service and fringe benefits are exceptional and in addition to a competitive salary, assistance with relocation expenses will be given where appropriate.

Please write with concise details of your qualifications and experience to:

Miss R. Curtis
Roussel Laboratories Ltd.,
Covingham, SWINDON,
Wilts. SN3 5BZ.

ROUSSEL

(192)

UNIVERSITY OF RIYADH MEDICAL SCHOOL SAUDI ARABIA

(IN ASSOCIATION WITH THE UNIVERSITY OF LONDON)

Applications are invited from male honours graduates for the following posts in the Medical School at the University of Riyadh. The vacancies which are for the pre-medical years have arisen as a result of the rapid expansion of the Medical School:

BIOLOGY—LECTURER/ASSISTANT LECTURER

BIOSTATISTICS—LECTURER

Applicants should have a higher degree and teaching experience.

Salary scale: Lecturers SR4,200 to SR5,200 per month plus a housing allowance of SR8,000 per annum; Assistant Lecturers—negotiable according to qualifications and experience. (£1 sterling=Saudi Ryals 8.80).

The University of Riyadh is an independent University established in 1957. In 1968 the University established a Medical School in association with the University of London. The request by the University of Riyadh for assistance in this project is covered by a sponsorship agreement. The University of London advises on the curriculum, the form and conduct of examinations, the physical facilities for teaching, the appointment of academic staff and other matters. From the outset it has been anticipated that this assistance would continue over a period of at least 10 years possibly extending to 15 years. All teaching of medical undergraduates is in the English language.

Appointments are for 1 year or longer; renewable. Secondments would be considered.

Detailed applications (3 copies) including a curriculum vitae and naming three referees should be sent not later than July 26, 1974 to the Inter-University Council for Higher Education Overseas, 90/91 Tottenham Court Road, London W1P 0DT from whom further particulars are available. (151)

CELLULAR IMMUNOLOGIST

Research appointment available for independent studies in the field of tumor immunology. Current ongoing programmes include studies on the mechanism of tumor cell destruction and the development of in vitro assays for estimation of cell mediated immune responses.

Preference given to experienced Ph.D., but active consideration given to imminent or newly graduated Ph.D. with strong immunology background. Salary open. Send curriculum vitae and names of three references to:

Dr C. S. Henney
The O'Neill Research Laboratories
Johns Hopkins University School of Medicine
at the Good Samaritan Hospital
5601 Loch Raven Blvd.
Baltimore, Maryland 21239, U.S.A.
An equal opportunity employer. (183)

STRANGEWAYS RESEARCH

LABORATORY WORT'S CAUSEWAY CAMBRIDGE CB1 4RN CELL BIOLOGIST

A postdoctoral position is available to work on the basic mechanisms of connective tissue metabolism. The candidate should have a sound background in cell biology but experience in connective tissue research is not essential.

The starting salary is £2,223 per annum with F.S.S.U. benefits. The appointment is for one year initially, but may be renewed for up to three years.

Please send curriculum vitae and names of two referees to Dr. J. J. Reynolds, Tissue Physiology Department, Strangeways Research Laboratory, Wort's Causeway, Cambridge CB1 4RN. (164)

Imperial Chemical Industries Limited

AGRICULTURAL DIVISION

Billingham, Cleveland.

A vacancy exists for a

MATHEMATICIAN

to join an existing team of eight graduates at Billingham. ICI Agricultural Division operates a complex of very large plants incorporating much new Technology originating from within, or developed by the Division. The mathematical Section in Research and Development Department deals with a wide variety of problems in chemical engineering theory, in the support of plant design and operation, and in some areas of mathematical planning. Candidates should have a good honours degree and an interest in applications such as reactor theory and fluid mechanics or statistics and operational research. Although a mathematics degree is preferred, candidates qualified in mathematical physics or in chemical engineering with a strong theoretical bias would be considered.

The section has good computer facilities, and candidates should possess or be ready to acquire competence in modern computing methods and programming.

The Company operates house purchase, profit sharing and contributory pension schemes and offers financial assistance towards removal expenses for married men.

Write giving brief details of age, qualifications and experience to:—

Mr M A J W Pegg

Personnel Department

Imperial Chemical Industries Limited

Agricultural Division

PO Box No 1 Billingham, Cleveland.

(205)

BASIC GRADE BIOCHEMIST

for Biochemistry Laboratory. Well equipped department offering good training facilities including radioimmunoassay techniques. Good Honours degree in Chemistry or Biochemistry required. Whitley Council conditions apply. Please reply with full details and names and addresses of 2 referees to Top Grade Biochemist, West Park Hospital Laboratories, Epsom, Surrey KT19 8PB. (158)

UNIVERSITY OF NATAL DEPARTMENT OF PHYSICS DURBAN

Applications are invited from suitably qualified persons for appointment to two posts of

LECTURER

In addition to teaching, successful candidates will be expected to take part in the experimental or theoretical activities of one of the research groups of the Department. The fields of interest are—

- (i) Magnetosphere Physics
- (ii) Laboratory Plasma Physics
- (iii) Electron Microscope studies of crystal defects.

Previous experience in one of these fields will be an advantage.

The salary scale attached to the posts is: R4,800 by R300 to R6,900 per annum plus 15% pensionable allowance.

The commencing salary notch will be dependent on the qualifications and/or experience of the successful applicant. In addition, an annual vacation savings bonus up to R260 for married men and R130 for women and single men is payable, subject to Treasury regulations.

Application forms, further particulars of the post and information on pension, medical aid, staff bursary, housing loan and subsidy schemes, long leave conditions and travelling expenses on first appointment are obtainable from the Registrar, University of Natal, King George V Avenue, Durban, South Africa, with whom applications, on the prescribed form, must lodged not later than August 31, 1974, quoting Ref. Adv. 75/74. (162)

THE ROWETT RESEARCH INSTITUTE

BUCKSBURN, ABERDEEN AB2 9SB
FIELD INVESTIGATIONS OFFICER

Applications are invited from suitably qualified graduates for a post to examine the incidence and severity of trace metal deficiencies in cattle and sheep. Trials are being planned on farms in the northeast of Scotland, and these may later be extended. A graduate with a good honours degree in agriculture, or agricultural chemistry or a degree in veterinary science, is required to help to organise and to participate in this work. The appointment is for a period of 3 years in the Nutritional Biochemistry Department.

Salary ranges (which are currently under review): Scientific Officer £1,435 p.a. rising to £2,329 p.a. Higher Scientific Officer £2,221 p.a. rising to £2,854 p.a. Superannuation under F.S.S.U. with a non-pensionable allowance of 4½% of basic salary to offset contributions.

Salary placing will be in accordance with qualifications and experience but for entry to the higher grade, candidates should have had at least 2 years' appropriate post-qualifying experience.

Applications, with full details, together with the names of 2 referees, should be addressed to the Secretary of the Institute, from whom further particulars are available, by August 17, 1974. (163)

UNIVERSITY OF READING

Two Research Assistants required in Department of Soil Science. Applications are invited:

(a) From graduates in Physical Chemistry, Soil Science or agricultural chemistry to work on mechanisms of phosphate sorption by soil minerals.

(b) From graduates in Physics or Physical Chemistry to join a research group concerned with studies of Pore Space in soils and its effect on gas and water flow.

Position (a) is supported by a grant from A.R.C. and position (b) by a studentship awarded by M.A.S.S. Applicants should have obtained first or upper second class honours and will be expected to register for a higher degree.

Both positions provide support at current research council studentship rates plus fees.

Further details may be obtained from Professor D. J. Greenland, Department of Soil Science, University of Reading, London Road, Reading, Berks. (Ref: MN 29). (177)

UNIVERSITY OF BRISTOL

The University invites applications for the appointment of **DIRECTOR** of the Long Ashton Research Station, which will become vacant on August 1, 1975, on the retirement of Professor J. P. Hudson, M.B.E., G.M., M.Sc., Ph.D. The Director is a Professor of the University and Head of the Department of Agriculture and Horticulture. The post is graded in the rank of Deputy Chief Scientific Officer in the Agricultural Research Service at a salary of £7,279 to £8,080.

Suitably qualified candidates are invited to submit applications, together with the names and addresses of three referees, by October 21, 1974. Further particulars of the appointment may be obtained from the Secretary of the University, Senate House, Bristol BS8 1TH. (176)

THE GRASSLAND RESEARCH INSTITUTE

HURLEY, MAIDENHEAD, BERKSHIRE SL6 5LR

HEAD OF

AGRONOMY DEPARTMENT

Applications are invited for the above post which will become vacant from January 1, 1975. The Institute is grant-aided by the Agricultural Research Council and is an Associated Institution of the University of Reading.

The research programme of the Department is directed towards an understanding of how to grow and utilise grass and forage crops. The rôle and importance of the Department in the Institute is to be extended and will in future include work with grazing animals, and the assessment of management factors under a range of climatic and soil conditions.

Candidates should have a special knowledge of grass and forage crops, and experience of conducting and organising research in this field, and have a desire to translate scientific knowledge into agricultural practice.

The post is graded Senior Principal Scientific Officer on the scale of £6,300 to £7,141 per annum.

Superannuation under F.S.S.U. with a non-pensionable allowance of 4½% of salary to compensate for personal contributions.

Further information may be obtained from the Secretary to whom applications should be submitted before September 15, 1974. (175)

**ROTHAMSTED
EXPERIMENTAL STATION
HARPENDEN, HERTS. AL5 2JQ
SCIENTIFIC OFFICER**

required to help with the design, construction and development of specialised apparatus to be used in studies on coconut breeding.

The Overseas Development Administration is currently supporting work on mechanical systems for the extraction and processing of coconut pollen as part of a mass pollination programme aimed at improving coconut production. This temporary post (initially for a period of 1 year from September 1, 1974) has been provided to support work now being done at Rothamsted Experimental Station.

Qualifications: Pass degree, H.N.C., H.N.D., or equivalent. Practical ability in use of workshop equipment essential.

Salary in scale £1,435 to £2,329 per annum (under review) according to qualifications and experience. Superannuation with non-pensionable allowance of 5½% to offset personal contributions.

Applications to the Secretary quoting Ref. 2292 by August 22, 1974. (165)

**SURREY EDUCATION
COMMITTEE
EWELL COUNTY TECHNICAL
COLLEGE
REIGATE ROAD, EWELL, SURREY
DEPARTMENT OF BIOLOGICAL
SCIENCES**

Required as soon as possible:

LECTURER 1 to teach **CELL BIOLOGY** and/or **BIOCHEMISTRY** for H.N.C. in **MEDICAL LABORATORY SUBJECTS**. The College is an approved centre for this course. Some experience of medical **MICRO-BIOLOGY** or **HISTOPATHOLOGY** and an interest in research and problems of learning in the biomedical field would be advantageous.

Applicants with suitable experience will have the opportunity to teach to M.I.Biol. (Honours B.Sc.) level.

Salary: £1,800 to £2,874 per annum—for good honours graduate the scale is extended to £3,045 per annum. £118 London Allowance payable per annum. Generous relocation expenses and assistance with house purchase in approved cases.

Further information and application forms available from the Vice-Principal at the College upon receipt of a stamped addressed foolscap envelope. Applications to be returned within 14 days of the appearance of this advertisement. (173)

**THE UNIVERSITY OF MANCHESTER
RESEARCH ASSOCIATE IN
CHILD HEALTH**

Biochemist required with post-graduate research experience for this post in the Department of Child Health with a team investigating brain growth and development. Salary p.a. according to experience, up to £2,388 (£2,580 from October 1). Applications (quoting telephone number if possible) to Dr John Dobbing, Department of Child Health, Stopford Building, Manchester M13 9PT by July 20. Quoting ref: 152/74/N. (186)

**THE UNIVERSITY OF
LANCASTER**

Department of Biological Sciences

Applications are invited for a **LECTURESHIP** in either freshwater ecology or physiological ecology in the fields of plant/water relations or ion-uptake by plants.

Further particulars may be obtained (quoting reference L.832/D) from the Establishment Officer, University House, Bailrigg, Lancaster LA1 4YW, to whom applications (five copies), naming three referees, should be sent not later than July 28, 1974. (189)

Fisheries Research

Applications are invited for a permanent and pensionable post in the Fisheries Research Laboratory of the Department of Agriculture based at Coleraine, Co. Londonderry.

The successful applicant who may be appointed at Senior Scientific Officer, Higher Scientific Officer or Scientific Officer level will be required to undertake investigations primarily concerned with the rational exploitation of commercial species and the development of marine fish farming, particularly shellfish. A knowledge of population dynamics, culture of shellfish, and fish biology would be an advantage. Ability to drive would be an asset.

Senior Scientific Officer: £2,798-£3,895 (under review).

Over 25 and under 32 years of age with a first or second class Honours Degree in Zoology or Biology and at least 4 years relevant postgraduate experience, preferably in Fisheries Research.

Higher Scientific Officer: £2,221-£2,854 (under review).

Under 30 years of age with an Honours Degree as above and at least 2 years relevant post-graduate experience.

Scientific Officer: £1,435-£2,329 (under review).

Under 27 years of age with an Honours Degree as above.

Grading and commencing salary will be related to qualifications and experience.

Please write or telephone for an application form, quoting Ref. SB 186/74/N to Civil Service Commission, Clarendon House, Adelaide Street, Belfast BT2 8ND (telephone 0232-44300, ext. 26).

Completed forms must be returned to arrive not later than 25 July, 1974. (174)

**NORTHERN IRELAND
CIVIL SERVICE**

North East London Polytechnic

Faculty of Science

Department of Biological Science

Applications are invited for the following four

Research Assistant posts:-

- (1) To work under the supervision of Dr D. Bryce on the ecology of Diptera larvae in woodland soil.
- (2) To work under the supervision of Dr D. Bryce on the ecology of Chironomidae in a polluted river system.
- (3) To work under the supervision of Drs S. Ball and J. Humphreys on enzyme variation in coccidial parasites.
- (4) To work under the supervision of Dr K. J. Adams on investigations into the mechanisms of control of cell division.

For posts (1) and (2) candidates should have or expect to obtain a good honours degree or equivalent qualification in Biology, for post (3) a similar qualification in Biochemistry or Biology and for post (4) candidates should hold a good honours degree in the area of Cell/Molecular Biology or in Electronics and have an interest in the application of electronics to biological problems.

In each case the appointment will be initially for two years at a starting salary of £1,427 per annum and the successful applicant may be permitted to register for a higher degree of the C.N.A.A.

Application form and further details from:—

**Academic Staffing Officer (2),
North East London Polytechnic,
Forest Road, London, E17 4JB. Telephone: 01-527 2272. Ref: S/CF 132.**

Closing date: 25 July, 1974.

(181)

**UNIVERSITY COLLEGE DUBLIN
RESEARCH POSTS IN GENETICS
OF ANIMAL DEVELOPMENT**

A Postdoctoral Fellow and a Research Assistant are required for a 3-year project sponsored by the National Science Council, on the inheritance of appetite, and of muscle and fat development in animals. The project will involve research on mice and sheep in University College, Dublin and in the Agricultural Institute at Belclare, Co. Galway. Knowledge of quantitative genetics is essential.

Full details from:

**Dr J. C. McCarthy,
Faculty of Agriculture,
University College,
Glasnevin,
Dublin, 9,
IRELAND.**

(191)

S.U.N.Y. AT STONY BROOK

Several faculty positions at the Assistant and Associate Professor levels are available, beginning June, 1975, in the newly established Department of Pharmacological Sciences. Candidates with research interests in neurobiology, molecular biology, biochemistry or biophysics are sought. A minimum of two years postdoctoral experience is required. Closing date September 1, 1974. Send resume and references to Dr. Arthur P. Grollman, Chairman, Department of Pharmacological Sciences, S.U.N.Y. at Stony Brook, Stony Brook, New York 11790. An affirmative action, equal opportunity employer.

(182)

Research & Development Director £10,000 plus.

The Fertilizer Division of Fisons Limited produces and markets fertilizers throughout the UK and has a current annual turnover approaching £80m.

The Research & Development Director to be appointed will be directly responsible to the Managing Director for all research and development activities in process technology, chemistry and agronomy. He will control a main research unit and two outstations employing in total 350 people, of whom 80 are of graduate standard. Preferred age is 35-45. A five figure salary is envisaged plus car, good pension scheme and significant additional benefits. The appointment is based at Levington, near Ipswich, Suffolk.

The successful candidate will have a proven record of success at a senior level in the research and/or development field, not necessarily in a commercial organisation. Degree subject is less important than the ability to manage a multi-discipline R & D activity. A doctorate is preferred.

Please write briefly and in confidence to Mr. J. Mugliston, Divisional Director, Fisons Limited—Fertilizer Division, Felixstowe, Suffolk IP11 7LP.

(261)

BIOCHEMISTRY DEPARTMENT CHAIRMAN

STATE UNIVERSITY OF NEW YORK AT STONY BROOK

Nominations and applications for this appointment are invited. Qualifications should include an outstanding record of achievement in research, teaching and appropriate administrative experience.

The Department serves the educational needs of undergraduates in the College of Arts and Sciences, medical, dental and other students in the School of Basic Health Sciences and graduate students enrolled in PH.D. programs.

The State University of New York at Stony Brook is an Affirmative Action—Equal Opportunity Employer and encourages applications from women and members of American minority groups.

Appointment title and salary are dependent upon qualifications and experience. Send nominations and inquires to:

Dr Vincent P. Cirillo,
Chairman, Search Committee,
Department of Biochemistry,
State University of New York,
Stony Brook, New York 11794

(217)

BRENT AND HARROW AREA HEALTH AUTHORITY BRENT HEALTH DISTRICT

A vacancy occurs for a Technician or Junior Technician in the Cytology Section of the Histopathology Laboratory. Some experience preferred. This Laboratory deals with Gynaecological and non-Gynaecological Cytology as well as Chromosomal Examinations.

Further information from Chief Technician 01-965 5733 Ext. 385. Application forms from and returnable to:

Personnel Department (Ext. 610), Central Middlesex Hospital, Park Royal, London NW10 7NS. (180)

UNIVERSITY OF OXFORD POSTDOCTORAL BIOCHEMIST or CELL BIOLOGIST

required to work on mechanism of chromosome condensation at mitosis on grant from Cancer Research Campaign.

Applications and enquiries to Dr J. M. Barry, Department of Agricultural Science. (194)

UNIVERSITY OF READING DEPARTMENT OF MICROBIOLOGY

Applications are invited for a Postdoctoral Research Appointment to work on the purification and characterisation of the Tetramethylammonium Mono-oxygenase system of Bacteria. Candidates should be biochemists who have had experience in the techniques of Anzymology, protein purification and microbiology. Salary: £2,118 x £129 - £2,247 p.a. plus F.S.S.U.

A research assistant is also required to work on the biochemistry of the utilization of Ethors by micro-organisms. Applicants should be graduates in biochemistry or microbiology. The successful applicant will be required to isolate and culture micro-organisms, prepare and purify cell-free extracts and undertake biochemical studies on the enzymes of ether utilization. Salary scale £1,435 - £1,846 p.a.

These appointments are both for two years from October 1974 and are supported by S.R.C. grants.

Apply with curriculum vitae and the names of two referees, as soon as possible, to Dr. L. J. Zatman, Department of Microbiology, University of Reading, London Road, Reading, RG1 5AQ. (Ref: MN30). (199)

UNIVERSITY OF BRISTOL SCHOOL OF CHEMISTRY POSTDOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited for a Science Research Council Postdoctoral Research Assistantship to work on the calculation of scattering cross sections in gas phase molecular collisions. The work will be directed towards the interpretation of crossed molecular beam experiments which examine inelastic collisions. A background in collision theory or computing experience will be an advantage.

The appointment, which is for one year in the first instance, with a possible extension to two years, is available from October 1974. Salary range up to £2,247 per annum.

Applications, with curriculum vitae and names of two referees, to Dr. G. G. Balint-Kurti, School of Chemistry, Bristol University, Bristol BS8 1TS, as soon as possible. (203)

THE EAST OF SCOTLAND COLLEGE OF AGRICULTURE invites applications for the post of HEAD OF CROP HUSBANDRY ADVISORY AND DEVELOPMENT DEPARTMENT

Applicants should have knowledge of R. & D. and Advisory aspects of crop production.

Salary scale (under review) £4,341 to £5,994.

F.S.S.U. with non-pensionable pay supplement to offset contributions.

Further particulars and application form from the Secretary, The Edinburgh School of Agriculture, West Mains Road, Edinburgh EH9 3JG. (190)

**UNIVERSITY OF OXFORD
MICROBIOLOGY UNIT
DEPARTMENT OF BIOCHEMISTRY**

A Postdoctoral Research Assistantship is available, from October 1, 1974, to work on the synthesis of ribosomes by a mutant of *Escherichia coli*. The post is financed by the Medical Research Council and the initial salary is a present £1,821 p.a. The project is directed by Dr D. G. Wild from whom further information may be obtained and to whom applications should be sent. (193)

**HAWKER SIDDELEY AVIATION
LIMITED
Broughton Chester
FINANCIAL DIVISION
ASSISTANT FINANCIAL
ACCOUNTANT**

There exists an interesting position for a suitably qualified accountant or finalist (ACA or ACCA) to head our final accounts department. He will report directly to the Financial Accountant and be involved in the computation of weekly/monthly management reports, the preparation of final accounts, annual and four year forecasts and also be responsible for the nominal ledger and capital assets section.

This position is a monthly staff appointment and big Company employee benefits include contributory pension scheme with free life assurance, four weeks holiday after qualifying period, canteen facilities. A five day 37½ hour week is in operation. Please apply giving details of age experience and qualifications to Eryl V. Hughes, Employment Officer, Hawker Siddeley Aviation Limited, Broughton, Chester. Or telephone Chester 24646 Ext. 34. (200)

**JUNIOR TECHNICAL OFFICER
(HORMONES & BLOOD PRODUCTS)**

Applications are invited from recently qualified graduate CHEMISTS or BIOCHEMISTS for a post within the Division of Hormones & Blood Products. The successful applicant will join a group working on the isolation and identification of peptides and enzymes and on the development of chemical methods to complement bioassay techniques.

Salary on scale £1,407 - £2,073 including London Weighting. Salary award pending. The Institute is situated in pleasant surroundings close to Hampstead Underground Station. There is an active Sports & Social Club and Superannuation benefits.

Please apply quoting Ref. 0026 giving brief details (an application form will be sent to you) to R. S. Dunn, Personnel Officer, National Institute for Biological Standards & Control, Holly Hill, Hampstead, NW3 6RB. Tel: 435 2232 (198)

**THE QUEEN'S UNIVERSITY
OF BELFAST**

**CHAIR OF
PHYSIOLOGY**

Applications are invited for the second Chair of Physiology from 1st October, 1974 or such later date as may be arranged. The successful applicant will be responsible for the day to day running of the section of the department dealing with teaching and research in Histology. Candidates who have medical qualifications would be considered for a joint appointment with the Eastern Health & Social Services Board with a University salary of £7,125 with contributory pension rights under the F.S.S.U.; an additional salary is paid by the Eastern Health & Social Services Board on a sessional basis for hospital services undertaken over and above University duties. Candidates who are not medically qualified would hold the University Chair with a salary of £6,810, with F.S.S.U.

Applications should be received by 31st August, 1974. Further particulars may be obtained from The Personnel Officer, The Queen's University of Belfast, BT7 INN, Northern Ireland. (Please quote Ref. 74/N). (206)

Opportunity Overseas

St. Helena

Fisheries Adviser

To be fully associated with the operation of a Pilot Fishing Survey to be carried out over 1-2 years with the objective of increasing the country's fish supply to its domestic market and to train a Counterpart. Applicants should have a degree in a Natural Science and have 5 years postgraduate experience. Experience in pelagic and demersal tropical fishery especially with tunny and crayfish also required. Appointment for 3 years.

Salary in scale £3,750 to £5,250 p.a. plus a tax free overseas allowance in scale £150 to £670 p.a.

Other benefits include free family passages, paid leave, children's education allowances free accommodation and medical attention.

Applicants should normally be citizens of, and permanently resident in the United Kingdom.

For full details, application form and booklet about St Helena, please apply giving age and brief details of qualifications and experience to:

Appointments Officer

Ministry of Overseas Development

Room E301, Eland House
Stag Place, London, SW1E 5DH

(243)

UNIVERSITY OF CAPE TOWN

CHAIR OF MARINE GEOSCIENCE

Applications are invited for the newly created Max Sonnenberg Chair of Marine Geoscience, which the University hopes to fill at an early date. The salary scale is R8 100 x 300 - R9 900 per annum plus a 15% pensionable allowance.

Applicants should submit a full curriculum vitae indicating their teaching and research experience and interests, present salary, and the earliest date on which they could assume duty, and should furnish the names and addresses of three referees whom the University may consult.

Further information should be obtained from The Registrar, University of Cape Town, Private Bag, Rondebosch, C.P.

Applications must reach the registrar by 30th September, 1974.

Appointment will be subject to a satisfactory medical certificate and the University reserves the right to appoint a person other than one of the applicants or to make no appointment. (213)

Research Opportunities in Pharmacology

Smith Kline and French Laboratories Limited carry out a key rôle in an international research effort at laboratories based in Welwyn Garden City. Owing to expansion in various areas of our research programme we have vacancies in our Pharmacology Department for

A Senior Pharmacologist

preferably with at least 10 years postdoctoral experience in industrial or academic research in the general field of inflammation.

Post Doctoral and Graduate Pharmacologists

with Ph.D's, first degrees or the equivalent in pharmacology or a related subject and with an interest in research into aspects of the pharmacology of the cardiovascular, central nervous, digestive or reproductive systems or into aspects of toxicology of immunology.

Junior Pharmacologists

with H.N.C., O.N.C. or the equivalent, as well as those with lesser qualifications but with an interest in pharmacology. Day release will be allowed to enable suitable qualifications to be obtained at the company's expense.

You can expect to benefit from being part of a large organisation both in remuneration and career opportunities. Salary will depend on qualifications and experience in each post.

Those interested should write with brief career details to:

**A. Maltby, Personnel Officer,
Smith Kline and French Laboratories Limited,
Mundells,
Welwyn Garden City, Herts.**

(260)

A member of the worldwide **SmithKline Corporation**

The Lister Institute of Preventive Medicine

(University of London) Elstree, Herts.

requires a

BACTERIOLOGIST

to undertake investigative and developmental work on bacterial vaccines and therapeutic sera. This post is one of responsibility and offers plenty of scope for interesting and rewarding research; it is suitable for a worker with a doctoral degree or of comparable seniority. Salary in accordance with experience and qualifications. Superannuation under F.S.S.U.

Applications to:

Secretary, Lister Institute of Preventive Medicine, Elstree, Hertfordshire.

(239)

SOUTH GLAMORGAN AREA HEALTH AUTHORITY TENOVUS INSTITUTE FOR CANCER RESEARCH

HEATH, CARDIFF

SENIOR SCIENTIFIC OFFICER

required for the Supra-regional Steroid Assay Service Laboratory of the above Institute. Experience in steroid analysis necessary and knowledge of automated techniques useful.

SALARY: £2,964 to £3,843 according to age, qualifications and experience

APPLICATIONS: Forms available from and further particulars regarding the post may be obtained from Professor K. Griffiths, Institute Director (Tel. 755944, Ext. 2579).

(223)

THE UNIVERSITY OF MANCHESTER INSTITUTE OF SCIENCE AND TECHNOLOGY DEPARTMENT OF MATHEMATICS RESEARCH ASSISTANT

Applications are invited for the temporary post of Research Assistant in Theoretical and Experimental Polymer Rheology. The Department has a strong Group undertaking research in the Mechanics and Physics of Solids and Fluids, and it possesses excellent facilities for experimental investigations in Rheology. There is direct access to extensive computer facilities in the University and the Institute. The successful candidate will be either a mathematician who wishes to test theories experimentally or an experimental scientist, and he will normally be expected to pursue researching leading to a higher degree of the University.

Salary—£1,764 per annum with F.S.S.U. rising to £1,839 per annum for the second and any subsequent years.

Applications, giving details of education, experience and research interests should be addressed to Dr. A. Kaye, Mathematics Department, U.M.I.S.T., Sackville Street, Manchester, M60 1QD, not later than 26th July, 1974. (201)

INSTITUTE OF OPHTHALMOLOGY (UNIVERSITY OF LONDON)

Judd Street, London WC1H 9QS

RESEARCH ASSISTANT (GRADUATE)

required to join team concerned with pharmacological aspects of ocular inflammation. Salary £2,118 p.a. plus £162 London Allowance. Applications to Professor E. S. Perkins at above address, with names and addresses of two referees. (218)

THE LONDON HOSPITAL

and the

NORTH EAST THAMES REGIONAL HEALTH AUTHORITY

have vacancy for a Non-resident SENIOR REGISTRAR in the GERIATRIC SERVICE for The London Borough of Tower Hamlets. A large part of the successful candidate's time will be spent in the geriatric/psycho-geriatric assessment unit at The London Hospital (Mile End). He/she will also be a member of the Department of General Medicine and will have opportunities for further education in a special field. The post gives an opportunity for teaching in a comprehensive district geriatric service.

Applications (no forms provided), giving the names and addresses of three referees, should be received by July 27, 1974 and addressed to: The Medical Staffing Office, The London Hospital, Whitechapel E1 1BB. Further particulars can be obtained from Dr Silver, Mile End (01-980 4855). (219)

THE QUEEN'S UNIVERSITY OF BELFAST

DEPARTMENT OF CHEMISTRY

Applications are invited for two posts, tenable from 1st October, 1974, of RESEARCH ASSOCIATE (postdoctoral), and RESEARCH ASSISTANT for research in polymer chemistry. The work will be concerned with the use of ¹³C nmr spectroscopy to elucidate the structure of polymers, and with the preparation and use of isotactic polypropylenimine as a template polymer. Appointments will be made for one year in the first instance. Salary, at appropriate points according to experience, will be on the scales Research Associate £2,118 to £2,247 to £2,412; and Research Assistant £1,239 to £1,818.

Applications, giving the names of two referees, should be received by the Personnel Officer, The Queen's University of Belfast, BT7 1NN, Northern Ireland, Not later than 31st July 1974. (207)

Fermentation Microbiologists

Shell Research Limited have a number of vacancies in the Fermentation Division of their Woodstock Laboratory at Sittingbourne, Kent for scientists and technical assistants to work in a multi-disciplinary team on process research and development towards the manufacture of single cell protein.

Senior Microbiologist

A Senior Microbiologist is required to lead a team engaged in isolation and characterisation of new cultures, monitoring fermentation systems and studying interactions in mixed cultures. The work will involve the use of the laboratories' extensive continuous culture facilities and will play a central role in developing commercial processes. A mature graduate is required for this post, probably over 30 years of age, with proven ability and, preferably, with experience in microbial screening or taxonomy.

Microbiologists

There are two vacancies for graduates in microbiology to work on isolation and characterisation of cultures and to study symbiotic interaction. You should have a

good honours degree in microbiology; preference will be given to candidates with proven research ability.

Technical Assistants

Two Technical Assistants are required to work on microbial taxonomy and microbial control in fermentation processes. You should have an H.N.C. in applied biology or the equivalent in a relevant subject, basic training in microbiology and practical experience in standard microbial techniques. A further vacancy exists for a technical assistant to work on bench scale continuous fermentation systems. Preference will be given to those candidates with one or more 'A' levels in relevant subjects or equivalents who have had some basic training in microbiology and, preferably, experience with fermentation equipment.

The levels of appointment will depend on background and experience, and the salaries offered will be competitive.

Please write, giving full details regarding personal background and experience, indicating for which position you wish to apply, to Shell Research Limited, Recruitment Division (N), PNEL/34, Shell Centre, London SE1 7NA.

(226)

PHARMACOLOGISTS/ TOXICOLOGISTS

Honours Graduates with some experience required for Research and short and long term toxicological studies of compounds of potential therapeutic importance. Excellent opportunities for advancement in modern, well-equipped laboratory. Pension and Assurance Scheme. Application Forms from: The Secretary, Biorex Laboratories Ltd., Biorex House, Canonbury Villas, London N1 2HB. (209)

UNIVERSITY OF MANCHESTER DEPARTMENT OF MEDICAL BIOCHEMISTRY RESEARCH ASSOCIATE

A postdoctoral biochemist is required to work under the direction of Dr. S. Itzhaki on a research project supported by the Cystic Fibrosis Research Trust, studying factors affecting the uptake of macromolecules by cells. Appointment for one year initially from October 1st, at a salary of £2,118 p.a. Further particulars and application forms (returnable by July 29th) from the Registrar, The University, Manchester M13 9PL. Quote ref: 155/74/N. (215)

Technician-R&D

G. D. Searle are one of the world's leaders in medical research. Our Research and Development department at High Wycombe is engaged in fundamental work in the areas of Immunology, Biochemistry and Molecular Biology. A vacancy has arisen for a Technician to assist in the extraction and assessment of macromolecules for various biological activities.

Ideally you should have experience of working in a hospital or biochemical laboratory, and have a qualification up to HNC/IMLT level. Anyone about to leave school/college and who is keen to pursue a technical career, should also apply. Full training will be given, including the facility for part-time study.

An attractive commencing salary will be offered, and conditions of employment include 4 weeks' holiday in each full calendar year of employment, Pension Fund, Restaurant and an active Social Club. Assistance with moving will be given in appropriate circumstances.

Initially please contact H W Cooke, Personnel Manager, Research and Development, G D Searle & Co Ltd, Lane End Road, High Wycombe, Bucks, OR telephone him on High Wycombe 21124 ext. 130, quoting reference T/119.

The SEARLE logo, consisting of the word "SEARLE" in a bold, sans-serif font, enclosed within a black rectangular box.

(262)

Chemist/ Biochemist

for pollutants research up to £2,500p.a.

The expansion of the Department of Environmental Physiology has created the need for a young chemist or biochemist to join a team studying the toxicology of a variety of inhaled substances.

They will be responsible for the generation and monitoring of experimental test atmospheres and expected to develop new and improved systems of generation for a variety of gaseous and particulate pollutants. Therefore previous experience in the fields of particle size analysis, mass monitoring techniques, and quantitative analysis would be a distinct advantage. Salaries up to £2500 per annum are offered together with a pleasant working environment close to Huntingdon within easy reach of Cambridge and fast rail and road links to London, excellent fringe benefits including 4 weeks holiday and an active sports and social club.

Further information and application form can be obtained from:

Mrs. Nancy McCree, Recruitment Officer,
Huntingdon Research Centre,
Huntingdon, PE18 6ES,
Telephone Woolley 431, Ext. 251.

H.R.C.

(210)

THE UNIVERSITY OF MANCHESTER RESEARCH ASSOCIATE IN CHILD HEALTH

Biochemist required with postgraduate research experience for this post in the Department of Child Health with a team investigating brain growth and development. Salary p.a. according to experience, up to £2,388 (£2,580 from October 1st). Applications (quoting telephone number if possible) to Dr. John Dobbing, Department of Child Health, Stopford Building, Manchester, M13 9PT, by July 20th. Quote ref. 152/74/N.

(214)

UNIVERSITY OF RHODESIA FACULTY OF SCIENCE CHAIR BIOCHEMISTRY

Applications are invited for appointment to the Chair and Headship of the Department of Biochemistry.

Salary Scales and Conditions (Approx. Stg. equiv.): £7,430 by £277 to £8,812, (Approx. US\$ equiv.): \$18,008 by \$670 to \$21,359.

Family passages and allowance for transport of effects; installation loan; travel allowance for Sabbatical and Contact Visits; superannuation and medical aid schemes. For persons recruited from outside Rhodesia, unfurnished accommodation on or near the campus and within easy reach of good schools is guaranteed for up to three years.

Applications: Six copies, giving personal particulars (including full names, place and date of birth), qualifications, experience, and publications, and naming three referees, should be sent by **August 31, 1974** to the Assistant Registrar (Science), University of Rhodesia, P.O. Box MP.167, Mount Pleasant, Salisbury, Rhodesia, from whom further particulars may be obtained. Applicants from outside Southern Africa should send an additional copy to the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, from whom further information may also be obtained. (212)

ST. MARY'S HOSPITAL MEDICAL SCHOOL

(UNIVERSITY OF LONDON)

Paddington, London W2 1PG

Applications are invited from engineering and physics graduates and chartered engineers, with not less than four years postgraduate training/experience in applied electronics research, for an appointment in Bio-Engineering Department with team conducting applied research leading to design and development of novel instruments and devices for use in a variety of specialties. Current activities include projects in surgery, obstetrics and gynaecology, urology and bacteriology. Excellent facilities. Starting salary on scale the maximum of which is £3,285 plus £162 L.A. p.a. Further details from Dr R. E. Trotman. Apply, The Secretary. (197)

TECHNICIAN or JUNIOR TECHNICIAN

required to undertake general laboratory duties in new M.R.C. Mammalian Development Unit. Experience in histology, photography, or in vitro embryo culture desirable. Applicants should preferably have experience in a biological research laboratory, or hold a University degree in a relevant subject. Salary according to age and experience. Applications to Dr M. L. Buehr, M.R.C. Mammalian Development Unit, Wolfson House, 4 Stephenson Way, London NW1 2HE. (225)

GRADUATE IN BIOCHEMISTRY

or related fields required to join research group studying effects of diet on metabolism of carcinogens. It is hoped that the successful applicant will work for a degree of the University of London. Applications, giving full details of qualifications, to The Secretary, The Medical College of St Bartholomew's Hospital, West Smithfield, London EC1A 7BE quoting reference 661. (222)

Avon Area Health Authority (Teaching)

Area Physicist

Salary scale: £5190—£5919 plus responsibility allowance

The Avon Area Health Authority (T), in co-operation with the South Western Regional Health Authority, propose to appoint a Top Grade Physicist, with special responsibility allowance, to act as Head of the Avon Area Medical Physics Service and as Adviser on Medical Physics to the South Western Regional Health Authority.

The Appointment is consequent upon the retirement of Dr. H. F. Freundlich later this year.

Whitley Council Terms and Conditions of Service apply.

Applications, giving the names of two referees, should be sent by the **8th August, 1974**, to The Personnel Officer, Avon Area Health Authority (T), National Westminster Court, Little John St., Bristol, BS1 2EE (Tel. Bristol 293541), from whom further particulars may be obtained.

(238)

JUNIOR TECHNICIAN

required for a research project in the Department of Surgery. Apply in writing, stating age and giving details of education and experience, if any, to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting Ref. D.S.3. (195)

**GLASSHOUSE CROPS RESEARCH
INSTITUTE
SCIENTIFIC OFFICER**

required for Entomology Department to join team studying INSECT VIRUSES in relation to crop protection, involving careful, detailed laboratory work. Applicants should be over 21 with degree or equivalent qualification in virology or biochemistry. Salary within scale £1,435 to £2,329 (under review) according to qualifications and experience. Contributory superannuation scheme with additional allowance of 54% of salary to offset contributions. Further particulars from Secretary of the Institute, Worthing Road, Rustington, Littlehampton, Sussex, to whom applications giving full biographical details should be sent by 31 July. (208)

GUY'S HOSPITAL MEDICAL SCHOOL

Applications are invited from medical graduates for the post of Junior Lecturer or Lecturer (full time or part time) in the Department of Physiology. The duties include teaching practical physiology, with man as a subject, and with emphasis on relevance to medicine.

The person appointed will have opportunity to follow his own line of research or to join in with current work. There are excellent facilities for co-operative research with other departments, both academic and clinical. For a recently registered graduate there are good facilities for preparation for the examinations for higher diplomas.

Salary (October 1974 rates, full time) for Junior Lecturer £2,580 to £3,285 and for Lecturer £3,285 to £4,896, plus £162 London Allowance and F.S.S.U.

Application forms are obtainable from the Dean, Guy's Hospital Medical School, London Bridge SE1 9RT and should be returned not later than July 29, 1974. (221)

UNIVERSITY OF BIRMINGHAM

Applications are invited for the post of

CURATOR

of the University Botanic Gardens.

Candidates should possess the relevant horticultural qualifications and good practical experience. Previous experience in the organisation of botanic gardens for teaching and research purposes is desirable but not essential. Salary is from £2,817 to £3,201 according to experience and qualifications. Rented accommodation is available.

Please apply to:

The Senior Assistant Secretary,
University of Birmingham,
P.O. Box No. 363,
Birmingham B15 2TT.
Reference: 133/B/288.

(224)

**NATIONAL COUNCIL FOR
SCIENTIFIC RESEARCH**

Applications are invited for an immediate vacancy for a:

**SENIOR PRINCIPAL PROFESSIONAL
OFFICER IN ANIMAL PRODUCTION,
ANIMAL PRODUCTIVITY
RESEARCH UNIT**

Applicants must hold postgraduate University degrees in agriculture, animal science, veterinary science, or animal nutrition, animal physiology or animal management. Candidates should have extensive practical research experience. The successful candidate will be responsible for developing, in relation to the Animal Productivity Research Programme, policy on animal production research and supervising the work of the Research Unit. He would be required, under the direction of the Council to collaborate with Government Departments and parastatal organisations.

The salary scale is in the range of K7,000 by K200 to K7,600. A gratuity of 20 to 30 per cent, depending on the length of service is paid to non-Zambians. Travel and education allowances are available for minor dependent children. Comfortable accommodation with basic furniture will be provided at low rental.

Applications giving full personal details, qualification and experience and naming three referees should be sent to:

The Secretary-General,
National Council for Scientific Research,
P.O. Box CH. 158,
Chelston,
LUSAKA,
Zambia.

(228)

Graduates & Technicians

Metabolism & Pharmacokinetics with the international leaders

We are Europe's largest research unit operating in the field of Life Sciences. As a result of our rapid and continuing expansion there are new vacancies for graduates and technicians in our Department of Metabolism and Pharmacokinetics.

Candidates should possess or be studying for an appropriate qualification (HNC, MIBiol, GRIC, BSc, PhD). The work will involve studies of the metabolic fate and pharmacokinetics of labelled drugs, pesticides and food additives using radioisotopes. Relevant experience would be desirable but is not essential. Proven practical ability is of prime importance.

These vacancies provide an ideal opportunity for suitably qualified scientific staff to join one of the leading drug metabolism research groups in the UK. Attractive career opportunities based on merit exist. The centre is located near Huntingdon in an attractive part of the country with good access to London by road and rail. We offer excellent working conditions together with progressive general benefits, a competitive salary and the usual pension and other fringe benefits.

Please write or telephone for an application form to

**Mrs. Nancy McCree, Recruitment Officer,
Huntingdon Research Centre,
Huntingdon PE18 6ES.**

**Tel: Woolley (STD 048 086) 431,
quoting reference number 301.**

H.R.C.

(211)

Lister Institute of Preventive Medicine

(University of London)

Elstree, Herts.

PRODUCTION MANAGER

The Lister Institute requires a Manager to take charge of the production for human use of bacterial vaccines, virus vaccines and therapeutic sera at its Elstree Laboratories. Applicants must have considerable experience in the organisation and day to day running of a unit producing biological materials; and the person appointed will play a major part in planning and implementing a considerable expansion in production. The salary will be in accordance with experience and qualifications and will be appropriate to a post of this seniority. Superannuation under F.S.S.U.

Applications to: **The Secretary,
Lister Institute of Preventive Medicine,
Elstree, Hertfordshire.**

(240)

CSIRO**AUSTRALIA****DIVISION OF COMPUTING RESEARCH
CANBERRA****RESEARCH SCIENTIST**

The Commonwealth Scientific and Industrial Research Organisation has a broad charter for research into primary and secondary industry areas. The Organisation has approximately 6,500 employees—2,100 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

FIELD:**COMPUTER
STIMULATION OF
BIOLOGICAL SYSTEMS**

GENERAL: The Division of Computing Research, with headquarters in Canberra, A.C.T., has recently installed a CDC 76 (commonly called a 7600 computer). The capacity and expansion potential of the configuration provide an unsurpassed tool for research and development projects. A rapidly expanding network of mini computers at CSIRO research centres enables the concentration of interactive and batch work in Canberra. Currently twelve batch terminals and more than one hundred interactive terminals are connected.

Major research studies at present include simulation techniques, operating systems, computer languages, data-base management and artificial intelligence. A consulting service is also provided to other CSIRO Divisions covering all aspects of computer use including applications packages, data logging, numerical analysis and the methodology of modelling and simulation.

An increasingly important part of the Division's activities is concerned with computer modelling and simulation of systems having biological components. Projects of interest include insect and parasite control, plant and animal growth, nutrient cycling in grazed pastures, aquatic ecosystems and arid-zone ecosystems. Areas of research cover: continuous, discrete and specialised simulation languages, numerical methods for use with such languages, probabilistic processes, and hierarchical techniques for the modelling and optimisation of complex systems.

DUTIES: To conduct research on improved methods for the computer modelling and simulation of complex systems, with special reference to biological systems.

QUALIFICATIONS: A Ph.D. degree in an appropriate biological field or equivalent qualifications together with demonstrable research ability. Considerable computational skill and ability to develop computer models are desirable.

SALARY: The appointment will be made within the salary ranges of Research Scientist or Senior Research Scientist: \$A9,698 to \$A14,706 p.a.

TENURE: The position is available for an indefinite period and Australian Government Superannuation benefits are available.

Applications stating full personal and professional details, the names of at least two professional referees and quoting Reference Number 900/251, should reach:—

The Personnel Officer,
Australian Scientific Liaison Office,
64-78 Kingsway,
LONDON,
WC2B 6BD

Applications in U.S.A. and Canada should be sent to
The Counsellor (Scientific),
Embassy of Australia, 1601 Massachusetts Avenue, N.W.,
WASHINGTON, D.C. 20036, U.S.A.

by the 9th August, 1974.

(244)

**UNIVERSITY OF WESTERN
AUSTRALIA
PERTH**

CHAIR OF GEOLOGY

Applications are invited for the above-mentioned appointment which will become vacant on the retirement of Professor R. T. Pridar on December 31, 1975. No specific field of interest has been assigned to the position and specialists in any of the major areas of Geology will be considered. Policy regarding headships of departments in the University is currently under review, but it is intended that the appointee to the Chair will be Head of the Department of Geology for an initial term of at least three years.

The salary for a Professor is \$A19,614 (currently about £12,325) p.a. Benefits include superannuation similar to F.S.S.U., fares to Perth for appointee and dependent family, removal allowance, study leave and long service leave and housing loan scheme. Further information including conditions of appointment may be obtained from the Staffing Officer in the University, or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications in duplicate stating full personal particulars, qualifications, experience and the names and addresses of three referees should reach the Staffing Officer, University of Western Australia, Nedlands, Western Australia 6009, by August 17, 1974. (230)

**UNIVERSITY OF
NEWCASTLE UPON TYNE
DEPARTMENT OF PHARMACOLOGY
RESEARCH ASSOCIATE
(CLINICAL NEUROPHYSIOLOGIST)**

Applications are invited from medically qualified or other suitably qualified candidates, with experience in clinical neurology, for the post of Research Associate in Neurophysiology in the Department of Pharmacology to join a multidisciplinary research team investigating the actions of psychotropic drugs in man. The appointment will begin on October 1, 1974 (or earlier if possible) and will be for one year in the first instance, renewable up to a maximum of three years in all. Commencing salary according to age, qualifications and experience, will be within the following ranges:

Medically qualified £3,021 to £3,363 p.a.

Non-Medically qualified £2,118 to £2,931 p.a.

Applications giving the names of two referees should be submitted within three weeks of the appearance of this advertisement to Professor J. W. Thompson, Clinical Pharmacology Unit, 13 Framlington Place, Newcastle upon Tyne NE2 4AB from whom further information may be obtained if required. (232)

**UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF BIOLOGY
POSTGRADUATE RESEARCH
ASSISTANT**

Applications are invited for an M.R.C. funded Research Assistantship in a group studying the control of gene expression during blood cell differentiation, under the supervision of Dr N. Maclean. Applicants should have a good honours degree in biology, biochemistry or genetics, and may be permitted to register for a higher degree. In the latter case the salary will be appropriately reduced.

The appointment will be for three years from October 1, 1974 (one year in the first instance) and salary will be in a range up to £1,700 per annum.

Applications giving a curriculum vitae and the names of two referees should be sent to the Deputy Secretary's Section, The University, Southampton SO9 5NH, to arrive not later than July 22, 1974. Please quote reference Na/253/R. (233)

**UNIVERSITY OF LEICESTER
DEPARTMENT OF BIOCHEMISTRY
TECHNICIAN—GRADE 5
(PROTEIN CHEMISTRY)**

A TECHNICIAN will be required from October 1, 1974 in connection with research (Professor W. V. Shaw) into the structure, function, and evolution of proteins. The techniques used will include conventional and novel methods of peptide purification, and automated approaches to primary sequence determination. Applicants must have experience in Protein Chemistry.

Please write to Chief Technician, Department of Biochemistry, University of Leicester, Leicester LE1 7RH by August 15, 1974. (236)

Royal Hospital for Sick Children

Department of Pathology

Applications are invited for two vacancies

(1) **GRADUATE**, preferably postdoctoral for research into glycoprotein production by cultured cells in relation to Cystic Fibrosis. Previous experience in this field not essential.

(2) **GRADUATE AS TECHNICIAN** or **TECHNICIAN** for research on the lysosomal enzymes of cultured cells in inborn errors of metabolism. Previous experience in this field not essential.

Applications in writing, giving names and addresses of two referees to the Sector Administrator, Royal Hospital for Sick Children, 1 Billbank Terrace, Edinburgh EH9 1LN.

(227)

ST GEORGE'S HOSPITAL MEDICAL SCHOOL

(UNIVERSITY OF LONDON)

Tooting, London SW17 0QT

DEPARTMENT OF PHYSIOLOGY

HISTOLOGY TECHNICIAN GRADE 3

Applications are invited for the post of Technician Grade 3 to assist with an M.R.C. programme of research on experimental lung disease with emphasis on neurohistology and mucus production. This recently formed department has an active interest in light microscopy, histochemistry and electronmicroscopy of the lungs. Some experience in these techniques is preferable but is not a necessary requirement.

Salary scale £1,650 to £1,920 (under review) plus London Allowance, depending on experience.

Applications should give full details of qualifications, experience and present employment, and be sent to Professor J. G. Widdicombe at above address.

(237)

NATIONAL COUNCIL FOR SCIENTIFIC RESEARCH

Applications are invited from suitably qualified persons for the post of:

BIOMETRICIAN

Applicants must have post-graduate degree or experience in mathematics or statistics with considerable research experience in sampling and experimentation. Experience in sample survey techniques, and biometrics research is desirable.

The Unit is primarily a consulting group and collaborates with various research units of the Council in fields such as animal productivity, forestry and insect ecology. It also advises and assists organisations outside the Council on statistical problems.

Salary according to qualifications and experience on the salary scales indicated below but a higher salary would be offered to exceptionally well-qualified and experienced senior scientists.

Senior Professional Officers K4,680 by K240 to K5,640.

Principal Professional Officers K5,840 by K240 to K6,800.

For Zambians there is a superannuation scheme. Non-Zambians will be paid a gratuity of 25% of aggregate basic salary earned during service of not less than thirty months.

Accommodation will be provided on an economic rental basis but not exceeding 10% of basic salary. Hard furniture will be provided. For non-Zambians travel and educational allowances are available for minor dependent children attending school outside Zambia.

Applications giving full personal details, qualifications, experience and naming three referees should be submitted to

The Secretary-General,
National Council for Scientific Research,
P.O. Box CH. 158,
Chelston,
LUSAKA,
Zambia.

(229)

CSIRO

AUSTRALIA

DIVISION OF COMPUTING RESEARCH CANBERRA

RESEARCH SCIENTIST/ SENIOR RESEARCH SCIENTIST

The Commonwealth Scientific and Industrial Research Organisation has a broad charter for research into primary and secondary industry areas. The Organisation has approximately 6,500 employees—2,100 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

FIELD:

OPERATING SYSTEMS

GENERAL: The Division of Computing Research has a Control Data Cyber 76 Computer (commonly called a 7600) in Canberra. With processor capable of averaging fifteen million instructions per second, central memory exceeding three million characters, disc capacity of twelve hundred million characters, and with substantial expansion capacity, the configuration provides an unsurpassed tool for research and development projects.

The Cyber 76 computer is currently linked to a network of batch terminals by a Control Data 3600 Computer. This will be replaced by a pair of more powerful "front-end" computers in 1975.

A rapidly expanding network of mini computers at CSIRO research centres is linked by Australian Post Office data services and enables the concentration of interactive and batch work in Canberra. Currently, about thirty batch terminals and about two hundred interactive terminals are connected.

DUTIES: To work as part of a team engaged in maintenance and development of operating system software for both the Cyber 76 and the new front end computers. Members of the team are expected to take some responsibility for day-to-day system maintenance but will also need the ability to undertake original and major development projects without detailed supervision or guidance.

Areas of likely development include the provision of interactive access to the Cyber 76 and front end computers, job scheduling, archival file storage and connection to communication networks.

QUALIFICATIONS: A Ph.D. degree (or equivalent) in computing science, together with demonstrable research ability. Previous experience in operating systems work is essential.

SALARY: Appointment will be made within the ranges of Research Scientist or Senior Research Scientist: \$A9,698 to \$A14,706 p.a.

TENURE: This position is available for an indefinite period and Australian Government Superannuation benefits are available.

Applications stating full personal and professional details, the names of at least two professional referees and quoting Reference Number 900/248, should reach:

The Personnel Officer,
Australian Scientific Liaison Office,
64-78 Kingsway,
LONDON WC2B 6BD

by August 9, 1974.

Applications in U.S.A. and Canada should be sent to:

The Counsellor (Scientific),
Embassy of Australia, 1601 Massachusetts Avenue, N.W.,
WASHINGTON, D.C. 20036, U.S.A.

(246)

CSIRO**AUSTRALIA****DIVISION OF ANIMAL GENETICS****NORTH RYDE NSW**

RESEARCH SCIENTIST/ SENIOR RESEARCH SCIENTIST

The Commonwealth Scientific and Industrial Research Organisation has a broad charter for research into primary and secondary industry areas. The Organisation has approximately 6,500 employees—2,100 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

FIELD:

POPULATION AND QUANTITATIVE GENETICS, POULTRY

GENERAL: The Division of Animal Genetics is concerned with research in genetics which has immediate or potential application to animal production. It has field stations and laboratories at which sheep, beef and dairy cattle work is in progress, and a poultry unit located at the Divisional headquarters, North Ryde, N.S.W. The work of the headquarters laboratory also includes mice, *Drosophila*, *Paramecium*, microbial and viral genetics, molecular and developmental genetics and theoretical population genetics.

DUTIES: To cooperate with present staff in carrying out the current programme of research in the genetics of egg production and in the further development of that programme or of other relevant areas of the genetics of poultry production traits. The emphasis in the current programme is on selection for higher ovulation rate and on the genetics of variability of egg weight. The appointee will have adequate freedom to pursue personal interests, experimental or theoretical, within the overall programme.

QUALIFICATIONS: An appropriate Ph.D. degree or equivalent qualifications supported by satisfactory evidence of research ability. Satisfactory knowledge and experience of the statistical and computer methods applicable to analysis of population or quantitative genetics experiments are essential. Some experience of working with poultry would be an advantage.

SALARY: The appointment will be within the salary ranges of Research Scientist or Senior Research Scientist: \$A9,698 to \$A14,706 p.a.

TENURE: This position is available for an indefinite period and Australian Government Superannuation benefits are available.

Applications giving full personal and professional details, the names of at least two professional referees, and quoting Reference Number: 675/361 should reach:

The Personnel Officer,
Australian Scientific Liaison Office,
64-78 Kingsway,
LONDON WC2B 6BD

by August 9, 1974.

Applications in U.S.A. and Canada should be sent to:

The Counsellor (Scientific),
Embassy of Australia, 1601 Massachusetts Avenue, N.W.,
WASHINGTON, D.C. 20036, U.S.A.

(247)

UNIVERSITY OF CAMBRIDGE**DEPARTMENT OF ZOOLOGY**

Research Assistant to work with Dr M. Burrows on neuronal mechanisms of insect flight. This three year post is supported by the Nuffield Foundation. Salary £1,467 to £2,388 p.a. Apply to Dr M. Burrows, Department of Zoology, Downing Street, Cambridge CB2 3EJ. (241)

UNIVERSITY OF BIRMINGHAM**DEPARTMENT OF PHYSICS****RESEARCH ASSOCIATESHIP**

Applications are invited for an appointment of up to three years under a Science Research Council grant for 'Experimental study of scattering of light by liquid and solid helium'. Candidates should have a Ph.D. in Physics. Experience in Cryogenics or high resolution Spectroscopy an advantage.

Salary on scale: £1,758 to £2,412 (exceptionally £2,931). Plus F.S.S.U.

Applications (3 copies), naming 3 referees should be submitted to the Assistant Registrar (S), P.O. Box 363, Birmingham B15 2TT by August 12, 1974. Please quote reference: NP2. (250)

CALL FOR PAPERS

Third International Conference on the Physics and Chemistry of Asbestos Minerals, August 17-21, 1975.

The Conference will be held at Laval University in Quebec City, Canada. Those interested in presenting a paper should communicate without delay with Dr C. A. Olivier, Mineral Research Center, Department of Natural Resources of Quebec, Canada CIV 4C7.

Sessions on the following topics are planned:

Physics—Surface properties; Mechanical properties; Electrical properties; Magnetic properties; Electron microscopy.

Chemistry—Composition; Spectroscopy; Crystal structure; Solid state reactions (dehydration, oxidation, reduction); Reactions with solutions.

Geochemistry—Formation; Synthesis; Phase rule studies; Trace elements.

Technology—Progress in applications of the properties of asbestos to industrial processes and products (e.g. asbestos-cement, reinforced plastics; insulation materials; textiles, etc.).

Biological Research in Asbestos—Biochemical and Biophysical effects of asbestos minerals. (255)

NURSING OPPORTUNITIES IN AUSTRALIA**NATHALIA DISTRICT HOSPITAL**

NATHALIA, VICTORIA •

**GENERAL AND MIDWIFERY
SISTERS**

are invited to apply for two vacancies at this 18-bed hospital. Salary is currently \$A130.90 per week plus penalties with an above award payment of \$156.00 paid half yearly.

The hospital is modern and the nurses' home comfortable. Nathalia is situated in central Victoria in the Murray Valley and has a mild and sunny climate. Regular bus service to Melbourne and other provincial cities. All social and recreational facilities are available locally.

Help will be given successful appointees in travelling to Australia.

Apply without obligation to Matron B. Millar, District Hospital, Nathalia 3638, Australia. (256)

**AMGUEDDFA GENEDLAETHOL
CYMRU****NATIONAL MUSEUM OF WALES****APPOINTMENT OF****ARCHAEOLOGICAL CONSERVATOR**

Applications are invited for the new post of ARCHAEOLOGICAL CONSERVATOR (Research Assistant I or II) in the Department of Archaeology. The successful candidate will be in charge of the existing departmental laboratory, in which the conservation staff of the Council of Museums in Wales also enjoy facilities, and will be responsible to the Keeper of Archaeology. Applicants should have appropriate qualifications and experience in Conservation and particular knowledge of casting techniques and pottery restoration would be an advantage.

The grading of the post, either Research Assistant I (Salary scale £2,332 to £2,997) or Research Assistant II (Salary scale £1,507 to £2,445), and the starting salary in the appropriate grade will depend upon age, qualifications and experience. Contributory superannuation. Generous leave.

Further particulars and application forms may be obtained from the Secretary, National Museum of Wales, Cardiff CF1 3NP to whom applications should be sent by Monday, August 19, 1974. (257)

**NATIONAL INSTITUTE FOR
MEDICAL RESEARCH
MILL HILL, LONDON
JUNIOR TECHNICAL OFFICER**

required to assist on the functional characterisation of the muscarinic cholinergic receptor. This work involves both biochemical and pharmacological techniques. Applicants should preferably have a degree in a relevant field and laboratory experience. Salary on scale to £2,199 p.a. (under review). Please write giving details of age, experience and qualifications to J. H. Woodcock, Personnel Officer, N.I.M.R., The Ridgeway, Mill Hill, NW7 1AA, Tel: 01-959 3666, quoting ref: JTO/MP (251)

**THE BRITISH COUNCIL
invites applications for the following post:
LECTURER IN STRUCTURAL
GEOLOGY
(THAILAND)
UNIVERSITY OF CHIENGMAI**

Men preferred between 30 and 50. Master's degree from a British university; at least 5 years' relevant experience.

Salary: £3,541 to £4,710 p.a.

Benefits: Free furnished accommodation, overseas and education allowances; terminal grant.

Two-year contract, usually renewable for a further period. Return fares are usually paid. Local contracts are guaranteed by the British Council.

Please write, quoting the reference number, for further details and an application form to The British Council (Appointments), 29 Bressenden Place, London SW1E 5DD. (258)

**UNIVERSITY OF ST ANDREWS
RESEARCH STUDENTSHIP**

Applications are invited from suitably qualified graduates to work with Dr C. R. Strong in the Department of Biochemistry, University of St Andrews. The 3-year project would involve studies on the control of lipid metabolism in mammary tissue, with particular reference to fatty acid synthesis and esterification.

The value of the award is £695 per annum plus approved fees. Applicants should contact Dr C. R. Strong, Department of Biochemistry, University of St Andrews, North Street, St Andrews, Fife, from whom further particulars can be obtained. (259)

**UNIVERSITY OF ST ANDREWS
DEPARTMENT OF CHEMISTRY**

Applications are invited for a post of Research Assistant to work with Dr C. Thomson on the computational aspects of ab-initio studies of the electronic structure of unstable intermediates. The appointment will be financed by the S.R.C. and will be for two years from October 1974 at a salary of £1,400 by £100. The successful candidate should possess an Honours degree or equivalent qualification, and have some background knowledge of computational chemistry, and experience in Fortran programming. Applications should be submitted by July 31, 1974 to Dr C. Thomson, Department of Chemistry, The University, North Haugh, St Andrews, Fife KY16 9ST, Scotland, from whom further details of the project may be obtained. (248)

**ZOOLOGICAL SOCIETY
OF LONDON
RECORDER**

for the *Zoological Record*, a bibliography of the world's zoological literature. Duties include scanning literature and indexing of relevant material.

Applicants should possess a degree in Zoology. Linguistic ability and previous experience in information work would be helpful but not essential. Posts based at units at the British Library Lending Division, Boston Spa and the British Museum (Natural History).

Salary on scale £1,526 to £2,096 plus £175 London Weighting if applicable (salary and weighting under review).

Applications, with brief details, in writing to Managing Recorder, *Zoological Record*, P.O. Box 9, Wetherby, Yorkshire LS23 7EG by July 31. (264)

**CLYDE RIVER
PURIFICATION BOARD**

**Senior Assistant
Marine Survey Officer**

Applications are invited for the above position in a multi-disciplinary team of highly qualified scientists engaged in the investigation and control of pollution on the West Coast of Scotland. A background in physical oceanography or mathematical modelling would be advantageous but applications from workers in other relevant fields will receive serious consideration. The post will involve a considerable commitment to the efficient organisation and management of the section and the appointee will deputise for the Marine Survey Officer. The work of the section currently includes major investigations related to the siting of marine outfalls, long-term biological and chemical monitoring of the marine environment and the study of circulation and dispersal of pollutants in the Clyde Sea Area. The Board has appropriate laboratory facilities and instrumentation and a replacement 54 foot survey vessel is nearing completion.

The post is superannuable. Salary will be within the range of £3,360 to £3,858. An essential user car allowance is provided.

Applications stating age, qualifications and experience, together with the names and addresses of two referees should be submitted to the Acting Director, Rivers House, Murray Road, East Kilbride, Glasgow G75 0LA, not later than July 31, 1974.

(254)

**NEW ZEALAND
Ministry of Agriculture & Fisheries**

Applications are invited for the undermentioned vacancy:

**Vacancy Scientist (Pasture
Agronomy)
Invermay Agricultural
Research Centre**

SALARY: According to qualifications and experience.

DUTIES: To assist with a large programme of varietal, fertiliser, cultivation and crop rotation studies. Opportunity exists for independent research. Good field and laboratory facilities are available on 500 hectare station.

QUALIFICATIONS DESIRED: Ph.D. or M.Agr.Sc.

PASSAGES: Fares for appointee and his wife and family, will be paid.

INCIDENTAL EXPENSES: Up to NZ\$120 for a single man and NZ\$800 for a married man can be claimed to cover the cost of taking personal effects to New Zealand.

Application forms and general information are available from the High Commissioner for New Zealand, New Zealand House, Haymarket, London, SW1Y 4TQ, with whom applications will close on 22 August 1974.

Please quote reference P/T 105 when enquiring.

(216)

**British Museum (Natural History)
Department of Mineralogy**

Analytical Chemist

■ Undertake chemical analysis of rocks, meteorites and minerals using classical and modern instrumental techniques.

□ Degree, HNC or equivalent in Chemistry □ Age under 27 □ Appointment as Scientific Officer (£1900-£3000). □ Ref: SB/31/DK.

□ Application forms (for return by 6 August 1974) from Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service).

**Ministry of Agriculture,
Fisheries and Food
Pest Infestation Control
Laboratory, Slough**

Information Scientist

■ To join Pesticides Survey Group, obtaining data on the uses of pesticides in food storage practice, animal husbandry and public health fields ■ Assist with design of surveys and draft questionnaires

■ Visit sample organisations ■ Process data and prepare reports.

□ Degree or equivalent in a biological or physical science □ 5 years' post-graduate experience (2 years' if good honours) □ Knowledge of Statistics and Computers, particularly in the data processing field, an advantage □ Age under 30 □ Appointment as Higher Scientific Officer (over £2550-around £3500) □ Ref: SB/9/AF.

Chemist

■ To work in the Pesticides Regulatory Section ■ Preparation of technical documents and reports on the chemistry, toxicology and related safety aspects of pesticides ■ Attend technical committees, and liaise with industry, universities and other government departments on new pest control techniques.

□ Degree or equivalent in chemistry or biochemistry □ Age under 27 □ Appointment as Scientific Officer (£1700-around £2800) □ Ref: SB/8/AF.

□ Application forms (for return by 2 August 1974) from Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB or telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service).

(242)

FELLOWSHIPS AND STUDENTSHIPS

**UNIVERSITY OF MANCHESTER
DEPARTMENT OF CHEMISTRY
POSTGRADUATE STUDENTSHIP**

Applications are invited for an S.R.C.-C.A.S.E. studentship to work on the mechanism of chelation and demetallisation of metal complexes with Dr. J. A. Connor and in collaboration with Dr. R. Price of I.C.I. Organics Division. The project will involve both preparative organic and inorganic chemistry together with the application of physical methods of measurement in the elucidation of a problem which is of basic importance to transition metal chemistry and of significance to the dyestuffs and metallurgical industries. Applicants should write as soon as possible to Dr. J. A. Connor, Department of Chemistry, University of Manchester, Manchester M13 9PL. (54)

**ROYAL FREE HOSPITAL SCHOOL
OF MEDICINE
DEPARTMENT OF BIOLOGY
POSTDOCTORAL RESEARCH**

Applications are invited from graduates in pharmacology or related subjects for a three-year research post at the postdoctoral level, supported by The Nuffield Foundation. The project concerns the rôle of genetic variation in the ability to metabolise foreign substances in the mouse. Starting date October or November 1974. Technical help will be available.

Salary £2,091 to £2,220 to £2,385 p.a. Plus F.S.S.U. Applications, with curriculum vitae and two referees, to Dr. I. E. Lush, Department of Biology, Royal Free Hospital School of Medicine, 8 Hunter Street, London WC1N 1BP. (94)

**FELLOWSHIP IN SALMON
DISEASES**

Applications are invited by the Atlantic Salmon Research Trust for a Research Fellow to be based at the Farran Laboratory of the Salmon Research Trust of Ireland, Newport, Co. Mayo, Ireland, in association with the Unit of Aquatic Pathobiology of the University of Stirling, with whom the successful candidate will be expected to register for a Ph.D. Application forms and conditions of service are available from the Director, Atlantic Salmon Research Trust Ltd., 29 South Street, Farnham, Surrey. Completed application forms to be received by July 31. (90)

**INSTITUTE OF CHILD HEALTH
(UNIVERSITY OF LONDON)
RESEARCH STUDENTSHIP**

Applications are invited from Honours Graduates in Biochemistry for a 3-year research studentship at the Institute of Child Health. The work will be concerned with certain aspects of vitamin E transport in the small intestine both in the experimental animal and patients, and the successful candidate will be expected to register for a higher degree. Starting salary £1,506 p.a. Applicants should send their curriculum vitae and the names of 2 referees to Professor O. H. Wolff, Department of Child Health, Institute of Child Health, 30 Guilford Street, London WC1N 1EH. (166)

**Esro Fellowship in
Infrared Astronomy**

Applications are invited from experienced infra-red astronomers for Fellowships to work in the Astronomy Division, ESTEC, on Michelson instrumentation for measurements of the ionic fine structure lines in HII regions and on the heterodyne detection of molecular line emission at sub-millimeter wavelengths. Aircraft and balloon borne telescope will be used.

Candidates must hold a Ph.D. in a relevant field of research.

The posts are tenable for up to two years. Further information can be obtained from

Head of Personnel
European Space Research
and Technology Centre
Domeinweg
Noordwijk
Holland.

(157)

UNIVERSITY OF READING

Applications are invited for an S.R.C., C.A.S.E. Studentship in Colloid Science leading to the Ph.D. degree for work on the stability of emulsions. The work will be carried out jointly with I.C.I. Plastics Division, Welwyn. Applicants should possess a good honours degree in chemistry or equivalent. Apply to Dr T. M. Hardman, Department of Chemistry, The University, Whiteknights, Reading RG6 2AD. (Ref: MN 28). (178)

**ROYAL FREE HOSPITAL
SCHOOL OF MEDICINE
DEPARTMENT OF BIOCHEMISTRY
AND CHEMISTRY**

Applications are invited from graduates with a 1st or upper 2nd class Honours degree in Biochemistry or other relevant subject, or from those graduating this year, for an S.R.C. Research Studentship tenable from October 1, 1974, leading to a higher degree in the University of London. Applicants should send a curriculum vitae and the names of two referees, as soon as possible, to Professor J. A. Lucy, Royal Free Hospital School of Medicine, 8 Hunter Street, London WC1N 1BP. (187)

AUSTRALIA

Queen Elizabeth II FELLOWSHIPS

in the Physical and Biological Sciences

To commemorate the Royal Visit to Australia in 1963 the Australian Government established the Queen Elizabeth II Fellowships Scheme. Under this scheme up to ten fellowships may be awarded each year for full-time research by young scientists of exceptional promise and proved capacity for original work. These are post-doctoral awards tenable in an Australian university or approved research institution normally for two years. Tenure of a Fellowship is expected to commence within nine months of the announcement of the award.

QUALIFICATIONS Queen Elizabeth II Fellows must be either Australian or United Kingdom citizens. They should have a Ph.D., or equivalent qualifications in one of the physical or biological sciences (which are deemed to include mathematics and the scientific aspects of statistics, engineering, metallurgy, agriculture and medicine).

Awards will in general be restricted to applicants who are not more than 30 years of age on the date when applications close.

STIPEND \$9,500 (Australian) per annum – increased to \$10,250 per annum at age 28 years.

ALLOWANCES are payable in respect of a Fellow's wife (\$500 p.a.), each dependent child (\$200), superannuation payments (up to 10 per cent of stipend), appropriate insurance coverage and necessary travel expenses. Host institutions are paid an allowance towards the cost of setting up the fellow and his research work.

APPLICATIONS Persons interested in applying for the above fellowships should obtain application forms and a statement of the conditions of award from the Secretary, Queen Elizabeth Fellowships Committee, Department of Science, P.O. Box 449, Woden, A.C.T., 2606, Australia; Education Liaison Officer, Canberra House, Strand, London, WC2R 3EH, England; or The Consul General, Australian Consulate General, 636 Fifth Avenue, New York 20, N.Y., 10020 U.S.A. Applications for the next round of awards which will be announced in December 1974 close at the Canberra address on 6th September 1974.

NEWCASTLE UPON TYNE POLYTECHNIC

Ellison Building, Ellison Place, Newcastle upon Tyne NE1 8ST

DEPARTMENT OF MATERIALS SCIENCE

RESEARCH FELLOW

This post is concerned with the development of plastics reinforced with carbon and other fibres for medical and dental applications. Candidates should have at least two years postgraduate research experience, preferably on engineering aspects of the use of materials.

RESEARCH ASSISTANTSHIPS AND STUDENTSHIPS

Several posts are available for work on the following topics:

- (1) Mechanical Properties of Composite Materials.
- (2) Spectroscopic Studies (I.R., N.M.R., Raman) on
 - (a) Structure and Properties of Polymers.
 - (b) Structure and Properties of Biological Materials.
- (3) Thermal Behaviour of Polymers Including the Effects of Fire on Structural Materials.
- (4) Studies on the Application of Polymer Films in Spectroscopy and Medicine.

Candidates should have or expect to have a good first degree or professional qualification in an appropriate science or technology, and must be eligible to register for a higher degree (M.Phil., Ph.D.).

RESEARCH TECHNICIAN

Candidates should have a good knowledge of electronics and instrumentation, and will be required to operate and maintain a wide range of equipment associated with the research laboratories.

All posts described above will be under the supervision of Dr T. R. Manley.
Salary Scales:

- Research Fellowship—£1,926 to £2,235.
- Research Assistantships—£1,200 to £1,500 (under review).
- Research Studentships—S.R.C. rates.
- Research Technician—£1,242 to £1,644.

For further details and application forms, returnable by August 7, 1974, send stamped addressed foolscap envelope to the Chief Administrative Officer. (185)

UNIVERSITY OF STRATHCLYDE

DEPARTMENT OF PURE AND APPLIED CHEMISTRY

SENIOR RESEARCH FELLOWSHIPS IN SYSTEMS STUDY OF INTENSIVE FOOD PRODUCTION PROCESSES

Applications are invited for two Fellowships that will appeal to graduates between 24 and 28 years of age, who, already having experience in their profession, would enjoy thinking in a broader perspective touching on futures research. No particular qualification is prescribed since the members of study group will be complementary, but appointees are likely to have experience in more than one of the following: microbiology, food science, food processing, chemical plant design or operation, thermodynamics, physical chemistry or system dynamics. An interest in economics and systems would be useful.

The Fellowships are tenable for two years from September 1974 at a salary up to £3,000 per annum with F.S.S.U.

Applications and enquiries (quoting R23/74) should be addressed to Dr M. Slesser, Department of Pure and Applied Chemistry, University of Strathclyde, Thomas Graham Building, 295 Cathedral Street, Glasgow G1 1XL, as soon as possible. (172)

THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF CHEMISTRY

Applications are invited for a POSTDOCTORAL RESEARCH FELLOWSHIP for studies on chemical carcinogenesis. The appointee will join a team working on chemical and biochemical aspects of polycyclic aromatic hydrocarbon binding to DNA, ranging from synthetic and structural organic chemistry to tissue culture. Candidates should hold (or expect to gain) a Ph.D. in organic or biological chemistry and experience in nucleic acid chemistry is desirable but not essential. Tenable from October 1, 1974 or a date to be arranged until September 10, 1975 at a salary not less than £1,923 per annum plus F.S.S.U. Applications, including a curriculum vitae and names and addresses of two referees to: Dr G. M. Blackburn, Department of Chemistry, The University, Sheffield S3 7HF. Please quote reference R106/G. (156)

UNIVERSITY OF MANCHESTER

A Research Fellow and a graduate Research Assistant required to work on the immunology of bladder cancer. The Fellow should have previous experience of cellular immunology and tissue culture techniques and may have either medical or scientific qualifications. Postgraduate experience is not essential for the Research Assistant post, and the successful candidate may be able to register for a postgraduate degree. Both appointments are for 3 years. Salary p.a. according to age, experience and qualifications (maximum initial rate for the Fellowship, £3,000, for the Assistantship, £1,900). Applications, including a full curriculum vitae with names and addresses of two referees, as soon as possible to: Dr Geoffrey Taylor, Immunology Laboratory, University of Manchester, Stopford Building, Manchester M13 9PL. (188)

THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF OBSTETRICS AND GYNAECOLOGY

A M.R.C. Postgraduate Studentship is available in the above Department for research in Labour Ward data handling. Minimum qualification required: good second class honours in science or engineering. The Labour Ward includes a comprehensive patient monitoring system based on equipment designed in department. PDP 8/E computer available, currently used to analyse fetal heart rate data and predict fetal outcome; proposed to extend this facility to include more data from mother and baby. Applications to Dr R. J. Parsons, Lecturer in Medical Physics, Jessop Hospital for Women, Sheffield S3 7RE, as soon as possible. Quote Ref. R.107/G. (170)

UNIVERSITY OF LONDON

INSTITUTE OF PSYCHIATRY

M.R.C. RESEARCH STUDENTSHIPS

available for candidates with good Honours Degrees in Physiology, Pharmacology or Biochemistry wishing to study for a Ph.D.

Apply immediately to Department of Neurology, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF or telephone 01-703 5411 ext 136. (196)

AUSTRALIAN NATIONAL UNIVERSITY

JOHN CURTIN SCHOOL OF MEDICAL RESEARCH

RESEARCH FELLOW/SENIOR RESEARCH FELLOW IN PHARMACOLOGY

Applications are invited for appointment as Research Fellow or Senior Research Fellow in the Department of Pharmacology (Head: Professor D. R. Curtis, F.A.A., F.R.S.). Applicants will be expected to have research experience in either neuropharmacology using micro-electrophoretic techniques (Professor D. R. Curtis), neuro-chemistry or organic chemistry of centrally active compounds (Dr. G. A. R. Johnston).

Further information may be obtained from Professor Curtis (July-September c/o Department of Pharmacology, University of Cambridge, Hills Road, Cambridge CB2 2QD) or Dr Johnston, in the University.

Closing date: August 1, 1974.

RESEARCH SCHOOL OF BIOLOGICAL SCIENCES

RESEARCH FELLOW

DEPARTMENT OF ENVIRONMENTAL BIOLOGY

The Department (Head: Professor R. O. Slatyer, F.A.A.) has an active programme of research in plant and animal ecology and related areas of plant physiology. A post is now available for an ecologist interested in aspects of community or population ecology. Present interests in these subjects include: (a) Effects of environmental factors on the structure and function of communities and of whole ecosystems (b) First-order interactions between species within an ecosystem, e.g. competition between species dependent on similar physical or biotic resources, interactions between herbivore and plant, between predator and prey; (c) Higher order effects in which the interaction between species are mediated by the activity of other biotic factors in the system.

Applicants should have a Ph.D. in ecology or related areas of biology and an interest in the general areas described above. The Department has excellent facilities and support for both laboratory and field work, plus a strong team of technical supporting staff.

Closing date: August 2, 1974.

SALARIES: Salary on appointment will be in accordance with qualifications and experience within the ranges Senior Research Fellow SA13,163 to SA15,548 p.a.; Research Fellow SA9,002 to SA12,269 p.a.

OTHER CONDITIONS: Tenure: Senior Research Fellow and Research Fellow normally for three years with the possibility of extension to a maximum of five years.

Reasonable travel expenses are paid and assistance with accommodation is provided for an appointee from outside Canberra. Superannuation is on the F.S.S.U. pattern with supplementary benefits.

The University reserves the right not to make an appointment by invitation at any time.

Prospective applicants should write to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, for further particulars before applying. (231)

UNIVERSITY OF BATH
SCHOOL OF PHARMACY AND
PHARMACOLOGY
RESEARCH STUDENTSHIP

Applications are invited from good Honours students in Pharmacy, Pharmacology or Biochemistry for this industrially-sponsored award. The successful candidate will carry out a project concerned with the mode of action of a new anti-Parkinsonian drug, and which will involve both animal and clinical pharmacology. The award is for one year at the normal S.R.C. rate, and the appointee will be expected to register for an M.Sc. degree. Applications to Dr. P. H. Redfern, School of Pharmacy and Pharmacology, University of Bath, Bath BA2 7AY. (202)

UNIVERSITY OF BIRMINGHAM
CHEMISTRY DEPARTMENT
RESEARCH STUDENTSHIPS

A number of S.R.C. Research Studentships, C.A.S.E. Awards, Departmental Grants, etc., are available for suitably qualified Science graduates for work on a wide variety of topics in various branches of Chemistry. Excellent facilities are available for higher degree studies of chemical properties of carbohydrates, fluorocarbons, polymers, enzymes, various natural products, nucleic acids, etc. Please apply without delay to Professor M. Stacey, C.B.E., F.R.S., Chemistry Department, Birmingham University, P.O. Box 363, Edgbaston, Birmingham B15 2TT. Telephone No. 021-472 1301, Ext. 3100. (235)

UNIVERSITY OF LIVERPOOL

Department of Inorganic, Physical and Industrial Chemistry

RESEARCH STUDENTSHIPS

A number of S.R.C. studentships are available in the above department for research in various aspects of Inorganic and Physical Chemistry. Areas of current activity include: Chemistry of organoboron and organometallic compounds and transition metal complexes; combustion chemistry; radiation chemistry; radiochemistry; surface chemistry; diffusion processes in solids and in polymer films; spectroscopy (NMR and ESR); colloid science and crystal growth; polymer science; theoretical chemistry.

Studentships related to the S.R.C. Polymer Centre, Liverpool are also available. Present research interests include: synthesis of new monomers and polymers; mechanisms of polymerization processes; polymer morphology; physical properties of polymers in the solid state and in solution.

The studentships are tenable from 1st October 1974 and successful applicants will register for the degree of Ph.D. Applications, including academic qualifications, names of two referees and an indication of field of interest, should be sent to The Registrar, The University P.O. Box 147, LIVERPOOL L69 3BX. Quote ref. RV/N/276122. (204)

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF PHYSICS

NUFFIELD RESEARCH FELLOWSHIP

Applications are invited for this post, tenable in the first instance for two years, from candidates with good research experience in any of the fields in which research facilities are currently available e.g. high energy physics, nuclear structure physics, applied nuclear science (neutron and reactor physics, and medical applications), solid state physics (low temperatures, crystallography, Mossbauer spectroscopy etc.), University physics teaching methods.

Salary scale: £2,118 to £2,412 plus F.S.S.U.

Further particulars may be obtained from the Assistant Registrar (S), P.O. Box 363, Birmingham B15 2TT, to whom applications (3 copies), naming 3 referees should be submitted by August 12, 1974. Please quote ref.: NPI. (249)

UNIVERSITY OF NEW ENGLAND

ARMIDALE, NEW SOUTH WALES

**TEACHING FELLOW IN
GEOGRAPHY**

The appointee will assist in the teaching programme of the Department, both in the laboratories and in the field, for internal and external students in Geography and will also carry out research towards a higher degree in Geography. Candidates should have specialist training and experience in physical or human geography and should have at least a good Honours degree in Geography or, preferably, a Master's Degree. While ability in quantitative techniques is expected, preference may be given to candidates with experience of tutorial, external, or audio-visual teaching, or fieldwork in geography.

Salary: \$A5,985 to \$A7,285. Conditions of employment provide assistance with travel and removal expenses.

Appointments with an academic fellowship component may be considered. Such appointments will normally be for an initial period of three years and will be subject to confirmation in the light of satisfactory service and progress towards a degree at the end of the first year of service. Appointments may thereafter be extended annually on the recommendation of the Head of Department. Full time assistantships will in the first instance be normally for a period of not more than one year. However, appointments may be extended on the recommendation of the Head of Department by a subsequent period of three years.

Further information may be obtained from the Staff Officer, University of New England, Armidale, New South Wales, 2351, Australia with whom applications, together with a recent photograph, and the names and addresses of three referees, close on **August 2, 1974**. Applicants in the United Kingdom and Europe should forward an additional copy, by the same date, to the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, from whom further information may also be obtained. (253)

ROTHMANS FELLOWSHIPS

Applications are invited for Rothmans Fellowships which are awarded under the Rothmans University Endowment Fund set up by Rothmans of Pall Mall (Australia) Limited to enable Fellows to undertake postgraduate work within an Australian University.

Rothmans Fellowships are of an annual value of \$A8,100 up to \$A12,400. A Fellow may be paid travelling expenses incurred in taking up the Fellowship and returning to his home.

In addition, an amount of \$A1,000 per annum towards fees and expenses including the purchase and maintenance of equipment may be paid to the University where the Fellow is working.

A Fellow shall take up a Fellowship before attaining the age of twenty-eight. The Fellowships are open to graduates of any University who have had at least three years' postgraduate experience in research. The Fellowships are not open to permanent members of academic staff or applicants proceeding on sabbatical, study or other leave (including leave without pay). The Fellowships must be held at an Australian University.

Application forms and further details may be obtained from the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close on **September 13, 1974** with the Secretary, Rothmans University Endowment Fund, c/o The University of Sydney, N.S.W., Australia 2006. (252)

**RESEARCH STUDENTSHIP IN
MICROBIOLOGY**

Applications are invited from suitably qualified graduates for a S.R.C. C.A.S.E. studentship to study "Stabilisation of enzyme systems in micro-organisms" at Queen Elizabeth College (University of London) and Shell Research.

Applications to Dr H. J. Somerville, Woodstock Laboratory, Shell Research Limited, Sittingbourne, Kent ME9 8AG. (263)

LECTURES AND COURSES

BRITISH POSTGRADUATE MEDICAL FEDERATION
UNIVERSITY OF LONDON

Medical Rehabilitation

A two-week course in Medical Rehabilitation will be held from Monday, September 30 to Friday, October 11, 1974 in the Department of Rheumatology, The Middlesex Hospital, London W.1.

The course which will cover the organisation of medical, industrial and social services is primarily designed for consultants and senior registrars drawn from any specialty in the National Health Service and in particular geriatrics, neurology, orthopaedics and rheumatology, but applications will be considered from community physicians and other doctors with a special interest in the subject. The programme includes visits to a spinal injuries and limb fitting centre, medical rehabilitation centres, industrial rehabilitation units and skillcentres, the Royal National Orthopaedic Hospital and Nuffield Orthopaedic Centre, Oxford, the Disabled Living Foundation's Aid Centre and Queen Elizabeth's Foundation for the Disabled at Leatherhead.

Course fee: £40. Approved under the D.H.S.S. Advanced Postgraduate Training Scheme. Application forms and further details from: The Secretary (Rehabilitation Course), B.P.M.F., 33 Millman Street, London WC1N 3EJ. Closing date for applications: August 31, 1974. (220)

UNIVERSITY OF SWANSEA
College of
Swansea

**RESEARCH STUDENTSHIP IN
GENETICS**

The Medical Research Council is prepared to offer a postgraduate studentship to a suitably qualified graduate, commencing October 1, 1974. Applicants should hold a first or upper second class degree in Biological Science. The work will involve an investigation of the possible genetic activity of environmental chemicals. An interest in the assessment of the hazards of environmental pollutants would be an advantage.

Applications giving details of qualifications and the names of two referees should be sent to the Registrar/Secretary, University College of Swansea, Singleton Park, Swansea SA2 8PP, as soon as possible. (234)

Collected Nature

These specially designed Binders make attractive space-saving files for your **Nature**. Bound in durable black imitation leather, lined with grey deer skin and beautifully labelled, each binder will hold up to eighteen copies of **Nature**. Two volumes of **Nature** can be preserved in a single binder, (three binders will hold the six volumes published annually) and there is a white space on the spine to enable you to mark each binder with your own reference to the issues it contains.

These binders are offered for sale singly for £1.85 or in packs of three for £5.00. Both prices include postage by surface mail and V.A.T. To order please complete the coupon below and return it with the appropriate remittance.

NATURE, Macmillan Journals Limited, Brunel Road, Basingstoke, Hampshire RG21 2XS.

Please send me:

1 NATURE BINDER (I enclose £1.85)

3 NATURE BINDERS (I enclose £5.00)

(Payment may be made in any currency at the current rate of exchange)
Prices applicable only to orders received before the 30th June 1975.
Orders can only be serviced if accompanied by remittance, cheques should be made payable to Macmillan Journals Limited.

Differentiation

Differentiation, published bi-monthly, provides the opportunity for interdisciplinary communication. This journal offers up to date information and synthetic views of a problem underlining the whole biological phenomenon – differentiation. It aims to cover the following areas of study: embryonic differentiation, normal cell growth and division, carcinogenesis and the cancer problem as an aspect of cell differentiation, inter-tissue reactions in vivo and in vitro, genetic mosaicism, nucleo-cytoplasmic interactions, nuclear transplants, cell hybridization, evolutionary biology, membrane controls of the cell, plant evolution and differentiation, immunological events relevant to differentiation.

Recent papers include:

Degree of differentiation in non-proliferating cells of mammary carcinoma, C. V. Wylie, P. K. Nakane and G. B. Pierce. **DNA synthesis and the production of antibodies by lymphoid tissues**, G. Harris. **The principle of sequential dependence in cellular differentiation**, P. A. Riley. Edited by: Dimitri Viza. Faculté de Médecine Pitié Salpêtrière, Paris.

Annual subscription £20 (£22.00 U.S.A. and Canada). Prices applicable only to orders started before 31st December, 1974. Payment may be made in any currency at the current exchange rate. Orders must be accompanied by remittance. Cheques should be made payable to: Macmillan Journals Limited, Subscription Department, Brunel Road, Basingstoke, Hampshire RG21 2XS, England.

Molecular Biology comes of age

This special **Nature** Supplement has been reprinted as a separate publication. First published in the issue of 26th April 1974, '**Molecular Biology Comes of Age**' looks back on the circumstances surrounding the original appearance in **Nature** of Watson and Crick's revolutionary paper on the double helix structure of DNA in 1953. It discusses the development in Molecular Biology up to the present day as well as prospects for the future. Among the distinguished contributors are Crick, Pauling and Chargaff.

'**Molecular Biology Comes of Age**' takes a fascinating and critical look at a very controversial area of study and will therefore be of special interest to teachers and students as invaluable background material.

Reprints of '**Molecular Biology Comes of Age**' are now available in multiples of five copies at £1.10 surface mail, or £2.00 airmail (10 copies £2.20 or £4.00 and pro rata). Please order copies by completing the order form below and returning it with the appropriate fee.

Circulation Department, Macmillan Journals Limited, Brunel Road, Basingstoke, Hampshire RG21 2XS.

Please send me copies of '**Molecular Biology Comes of Age**', by surface mail/airmail (delete whichever is not applicable).

I enclose £

(Payment may be made in any currency at the current exchange rate. Orders must be accompanied by remittance. Cheques should be made payable to Macmillan Journals Limited.)

HAVE GLC, NEED RADIOGAS CHROMATOGRAPH?

Then simply add a Panax F.0112 radiogas detector system to it and you're in business! This high-resolution, low-background detector is supplied complete with furnace unit and NIM-type electronics, ready for instant coupling-up to virtually any make of GLC apparatus, old or new.

Counting efficiency is typically 95% for ^{14}C and 60% for $^3\text{H}_2$, giving an order of merit figure of more than 6000. Data-acquisition options include (1) twin-pen servo-driven potentiometric recorder, for simultaneous tracing of Mass and Radioactivity peaks; (2) scaler/printing-lister combination, for integrating activity under chart peaks (illustrated); (3) Teletype SR 33 and control unit, for results in both hard-copy and punched-tape formats.

May we send you our literature?

Cover picture

The orrery, an instrument for showing the position of the Earth and Moon relative to the Sun at a given date and time. This fine example of the instrument maker's craft was made by Rowley in about 1716, based on an original invention by Graham. Rowley presented it to the Fourth Earl of Orrery, after whom it was named. This orrery, the oldest instrument of its kind, has recently been purchased for £29,000 by the Science Museum from the present Earl of Cork and Orrery. (Science Museum photo, Crown Copyright).

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.

- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).

- 'Matters arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. $\exp(a)$ is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of *Nature*. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in *Nature* (246, 238; 1973).

Vaccinia virus cytotoxin(s)—J. Stephen, T. H. Birkbeck, C. G. Woodward and J. Wolstenholme	236

Physics and Chemistry in Space

Edited by J. G. Roederer, Denver, Colo.

A series of monographs written and published to serve the student, the teacher and the researcher with a clear and concise presentation of up-to-date topics of space exploration.

Editorial Board: H. Elsässer, Heidelberg; G. Elwert, Tübingen; L. G. Jacchia, Cambridge, Mass.; J. A. Jacobs, Edmonton, Can.; N. F. Ness, Greenbelt, Md.; W. Riedler, Graz

Volume 1

J. A. Jacobs: Geomagnetic Micro-pulsations

With 81 figs. VIII, 179 pp. 1970. Cloth DM 36,—; US \$13.90
ISBN 3-540-04986-X

Volume 2

J. G. Roederer: Dynamics of Geomagnetically Trapped Radiation

With 94 figs. XIV, 166 pp. 1970. Cloth DM 36,—; US \$13.90
ISBN 3-540-04987-8

Volume 3

I. Adler, J. I. Trombka: Geochemical Exploration of the Moon and Planets

With 129 figs. X, 243 pp. 1970. Cloth DM 58,—; US \$22.40
ISBN 3-540-05228-3

Volume 4

A. Omholt: The Optical Aurora

With 54 figs. XIII, 198 pp. 1971. Cloth DM 58,—; US \$22.40
ISBN 3-540-05486-3

Volume 5

A. J. Hundhausen: Coronal Expansion and Solar Wind

With 101 figs. XII, 238 pp. 1972. Cloth DM 68,—; US \$26.20
ISBN 3-540-05875-3

Volume 6

S. J. Bauer: Physics of Planetary Ionospheres

With 89 figs. VIII, 230 pp. 1973. Cloth DM 78,—; US \$30.10
ISBN 3-540-06173-8

Volume 7

Schulz/Lanzerotti: Particle Diffusion in the Radiation Belts

With 83 figs. Approx. 250 pages. 1974
Cloth DM 78,—; US \$30.10
ISBN 3-540-06398-6

Molecular Biology comes of age

This special *Nature* Supplement has been reprinted as a separate publication. First published in the issue of 26th April 1974, 'Molecular Biology Comes of Age' looks back on the circumstances surrounding the original appearance in *Nature* of Watson and Crick's revolutionary paper on the double helix structure of DNA in 1953. It discusses the development in Molecular Biology up to the present day as well as prospects for the future. Among the distinguished contributors are Crick, Pauling and Chargaff.

'Molecular Biology Comes of Age' takes a fascinating and critical look at a very controversial area of study and will therefore be of special interest to teachers and students as invaluable background material.

Reprints of 'Molecular Biology Comes of Age' are now available in multiples of five copies at £1.10 surface mail, or £2.00 airmail (10 copies £2.20 or £4.00 and pro rata). Please order copies by completing the order form below and returning it with the appropriate fee.

Circulation Department, Macmillan Journals Limited, Brunel Road, Basingstoke, Hampshire RG21 2XS.

Please send me copies of 'Molecular Biology Comes of Age', by surface mail/airmail (delete whichever is not applicable).

Britain takes up the SGHWR

AFTER four years of debate, during which it often seemed that no decision would ever be made, the government has finally jumped off the fence, bowling over Sir Arnold Weinstock and the Central Electricity Generating Board (CEGB) in the process. For, like it or not, the CEGB is going to have to order a small number of steam generating heavy water reactors (SGHWRs) in the next few years rather than a considerably larger number of the American pressurised water reactors (PWRs) which it favours.

The remarkable thing about all this is that the decision could equally well have been made in 1972 when Mr John Davies, then Secretary of State for Trade and Industry, announced a programme of component development for the SGHWR. Other options for the short term could still have been kept open and indeed that is exactly what Mr Eric Varley, Secretary of State for Energy, has done nearly two years afterwards in saying that the Nuclear Installations Inspectorate should complete its examination of the safety of the American reactors.

Even if Mr Davies had also opted for a relatively modest scheme, Mr Varley might now be in a position to enlarge a programme to which the nuclear power industry and the CEGB would have had two years to adjust. As it is, Sir Arnold, who is head of GEC (a 50% stakeholder in the National Nuclear Corporation), is sulking and threatening to reduce considerably, or even eliminate, his company's share in the corporation. That would be embarrassing, as GEC is supposed to manage the building of the next generation of nuclear reactors in Britain and it will no doubt cause wry smiles among members of the Select Committee on Science and Technology which thinks that a shareholding of more than 30% by any commercial interest should not have been allowed in the first place. In fact it is difficult to see how the corporation could continue if Sir Arnold were to depart completely.

Ultimately, however, it is the CEGB which has to generate the electricity and its views deserve the most sympathetic consideration. It is that body, one has to bear in mind, which still has all five advanced gas cooled reactor stations waiting to be completed almost ten years after the first one was ordered. Basically the CEGB wants to order nuclear power stations in such numbers over the next decade or so that its reliance on fossil fuel is decreased, and it wants those nuclear power stations to work properly. Not surprisingly, therefore, it criticises the government's decision on the grounds that the SGHWR is untried in a commercial situation and that because of this the government is only risking a programme of some 4,000 MW to be ordered over the next four years and commissioned in the 1980s. Even the quite modest rate

of growth of electricity demand now envisaged by the Department of Energy requires 35,000 MW of new capacity by 1990, the lion's share of which will evidently be based on fossil fuels unless the SGHWR turns out to be such a success that more can be rapidly ordered after the first has become operational, perhaps in 1981.

The CEGB points out, and the government apparently agrees, that more development work will have to be done before the SGHWR can be built on even the scale that Mr Varley envisages (small units of 660 MW). The argument goes that the test reactor at Winfrith is only 100 MW and is based on technology that is already 10 years old. Parts will have to be redesigned, says the CEGB, and different materials will have to be used. But is all this really necessary? Does a new piece of functional equipment necessarily have to incorporate the most up-to-date technology wherever possible? Excessive zeal in this direction would seem to be ill advised, especially if an attempt to wring that extra bit of efficiency or cost out of the system were to cause more expense in the long run than could ever be saved. After all the suggestion that more Magnox stations should be built is only a nonstarter because of the high capital cost compared with more modern reactor designs.

What the CEGB seem to overlook is that the Canadian CANDU reactor, which is similar in many ways to the SGHWR, has been working successfully for several years and that technological cooperation between Britain and Canada is thought by both countries to be a mutually advantageous prospect. And there seems no reason why Britain should not now take advantage of the export opportunities which may still exist for the SGHWR.

100 years ago

WE rejoice to see from the tone of the replies to questions in the House of Commons on Monday by Mr. Disraeli and Lord Henry Lennox, that Government is conscious of how poorly housed some of our scientific collections are, and seems really disposed to take steps to remedy the evil. Mr. Disraeli said, in reply to a question concerning the Patent Museum, that it is not the only public institution which is suffering from want of space and of suitable accommodation. "That is now a crying grievance with respect to all our public buildings, collections, and offices. In regard to the Patent Museum, however, I am aware from a communication which I have received from my noble friend the First Commissioner of Works, that the matter is at present engaging attention." Lord Henry Lennox confirmed this by subsequently stating that he intended to propose to Her Majesty's Government a scheme which, if it were agreed to, would enable him to offer the Patent Museum suitable accommodation in the southern block of the International Exhibition buildings.

From *Nature*, 10, 232, July 23, 1874.

NATO and civil science

Peter J. Smith, who once accepted a NATO Fellowship because it was the only support available for work in a nonuniversity research institution in the United States, discusses NATO's involvement in civil science.

WHAT is the connection between stress and anxiety in modern society, the chemistry of insects, cosmological models, and the mooring and berthing of ships? The answer is that in common with more than 50 other science-based activities they were the subjects of well financed conferences during 1972. On the face of it, of course, there is nothing very strange about that; it is a common enough occurrence for scientists to congregate with their colleagues around the world to discuss new results and ideas, and some of them even find it useful. But there is something a little odd about it in this case, for all 56 meetings were sponsored and paid for by a single organisation which has nothing directly to do with academic science at all—the North Atlantic Treaty Organisation (NATO). The question is: why?

Scientists do pretty well out of NATO, and not just in the matter of conferences. The total budget of the NATO Science Committee in 1972 was \$4.83 million of which only \$0.93 million went on scientific meetings. Well over half was spent on the Fellowship Programme. Research grants then accounted for a further \$0.61 million, and a few specialised programmes (such as operational research, oceanography and human factors) and administration took the rest.

The mandate for all this involvement in basic science is Article 2 of the North Atlantic Treaty (1949) by which “the Parties will contribute toward the future development of peaceful and friendly international relations by strengthening their free institutions, by bringing about a better understanding of the principles upon which those institutions are founded, and by promoting conditions of stability and well-being”. For the first eight years of NATO's existence the emphasis was clearly on “defence”; but in 1957 Paul Henri Spaak, the second Secretary General, made a serious attempt to widen the field to include ostensibly nonmilitary collaboration. One result was the establishment in 1958 of the

NATO Science Committee to “strengthen the Alliance and its political substance”—a form of words whose deeper meaning has apparently never been in doubt, for NATO has never made any secret of the fact that it sees its support for science as contributing, however indirectly, to its military and political aims.

In view of the often violent reaction against the military sponsorship of university science in recent years, a basically military organisation which not only publicises its involvement in civil science but also extols the virtues of it in print may appear at first sight to be either remarkably honest or incredibly naive. In fact, NATO is neither. It is not genuinely honest to be completely open about a participation which would surely be discovered in any case; and the charge of naivety would only be substantiated if it could be shown that members of the NATO Science Committee were unaware of the strength of feeling already expressed on the issue of military sponsorship. Moreover, to the extent that the sort of science sponsored by NATO furthers military aims no more nor less than it would if sponsored by an overtly civil body, financial aid from NATO as such would seem to have little relevance to that organisation's stated aims. One can only conclude, therefore, that NATO's public stance is designed to conceal motives which are altogether more subtle.

Indeed, what NATO has really been after from its large scale support of basic science—and what it has to a large extent achieved—is a sort of social respectability and prestige among a community containing elements who are decidedly touchy over the relationship between science and the military. Since 1959 over 10,000 NATO Fellows have written tens of thousands of legitimate scientific papers, each of which records gratitude for NATO support; every moderately sized scientific library in the world now contains hundreds of volumes bearing witness on their title pages to NATO's generosity; and every conference announcement implicitly proclaims NATO's apparent concern for disinterested scientific scholarship and culture. In addition, the NATO Science Committee has always gone out of its way to attract to membership established and high-ranking scientists or government scientific advisers who are able to confer their own brand of legitimacy on NATO's activities.

As might be expected, some scientists have argued that none of this matters—that given that the relevant activity is essentially nonmilitary, who pays for it is of no concern. Unfortunately, however, there is evidence that NATO's scientific involvement is

not entirely beneficial to science itself, even if motives are ignored. For one thing, although the Science Committee is always quick to point out that up to 20% of the participants in its conferences come from non-NATO countries, including the communist nations of eastern Europe, it is less ready to publicise the fact that non-NATO delegates are forbidden to attend on NATO funds. And in spite of boasts about participants from the Soviet Union and elsewhere, it is doubtful whether scientists from, say, Cuba or North Vietnam would be able to attend a NATO conference in the United States. In fact, as far as I know (and certainly up to the end of 1972), no scientist from either of these countries has ever attended any NATO conference anywhere.

Thus although scientists pride themselves on their international outlook, they are not above doing less than justice to their ideals for the sake of a quick buck. And it is because of this sort of opportunism—not to mention the skilful casuistry displayed in rationalising it—that NATO science has been given little opposition.

Few would suggest that military sponsorship is the most important problem facing civil science today. At the same time, however, this is far from saying that it is of no concern at all; and there is clearly a significant minority which feels sincerely that NATO involvement in particular is a blot on the scientific landscape. The irony is that the whole NATO sponsorship scheme is totally unnecessary, except perhaps as perceived by NATO itself. The fact is that the Fellowship programme, which accounts for about 60 per cent of the NATO science budget, is administered not by NATO but by agencies in the constituent countries (the Science Research Council in Britain, the National Science Foundation in the United States). A large proportion of NATO science money is thus returned directly whence it came (and almost all of it is repatriated to the constituent nations in one form or another), NATO's sole contributions being the use of its name and, as one cynic has pointed out, an addition to bureaucratic overheads. Since most of the national agencies concerned now have parallel programmes of their own, there seems to be little point in perpetuating NATO's involvement any longer. Alternatively, if an overtly international programme of science support is felt to be desirable, it would be far preferable to make it truly international and hand over the whole NATO scheme to some clearly nonmilitary organisation such as UNESCO. Presumably this would keep everyone happy—including NATO, if it really means what it says.

international news

NAS ban on plasmid engineering

"RECENT advances in techniques for the isolation and rejoining of segments of DNA now permit construction of biologically active recombinant DNA molecules *in vitro*. For example, techniques employing DNA restriction endonucleases, which generate DNA fragments containing cohesive ends especially suitable for rejoining, have been used to create new types of biologically functional bacterial plasmids carrying antibiotic resistance markers (Cohen *et al.*, *Proc. natn. Acad. Sci.*, **70**, 3240; 1973; Chang *et al.*, *Proc. natn. Acad. Sci.*, **71**, 1030; 1974) and to link *X. laevis* rDNA to DNA from a bacterial plasmid. This latter recombinant plasmid has been shown to replicate stably in *E. coli* where it synthesises RNA complementary to *X. laevis* rDNA (Morrow *et al.*, *Proc. natn. Acad. Sci.*, in the press). Similarly, segments of *Drosophila* chromosomal DNA have been incorporated into both plasmid and bacteriophage DNAs to yield hybrid molecules that can infect and replicate in *E. coli* (Hogness, unpublished; Davis, unpublished; Boyer, unpublished).

"Several groups of scientists are now planning to use this technology to create recombinant DNAs from a variety of other viral animal and bacterial sources. Although such experiments are likely to facilitate the solution of important theoretical and practical biological problems, they would also result in creation of novel types of infectious DNA elements whose biological properties cannot be completely predicted in advance.

"There is serious concern that some of these artificial recombinant DNA molecules could prove biologically hazardous. One potential hazard in current experiments derives from the need to use a bacterium like *E. coli* to clone the recombinant DNA molecules and to amplify their number. *E. coli* strains commonly reside in the human intestinal tract, and they are capable of exchanging genetic information with other types of bacteria, some of which are pathogenic to man. Thus, new DNA elements introduced into *E. coli* might

possibly become widely disseminated among human, bacterial, plant or animal populations with unpredictable effects.

"Concern for these emerging capabilities was raised by scientists attending the 1973 Gordon Research Conference on nucleic acids (Singer and Soll, *Science*, **181**, 1114; 1973), who requested that the National Academy of Sciences give consideration to these matters. The undersigned members of a committee, acting on behalf of and with the endorsement of the Assembly of Life

In an unprecedented move, the National Academy of Sciences has called for a voluntary worldwide moratorium to be placed on an area of scientific research because of potential and unpredictable hazards to human health. A statement drawn up by a committee of eminent biomedical scientists and released by the academy this week calls for a temporary halt on two types of genetic engineering research because of the risk of infecting man with bacteria containing hybrid DNA molecules whose biological properties cannot be predicted in advance.

The academy is concerned about experiments which combine fragments of DNA from different sources to form a hybrid molecule which can then replicate in bacteria such as *E. coli*, which is normally present in the human intestine. The Committee on Recombinant DNA Molecules, whose members* have all agreed individually to renounce two types of experiments involving such techniques until the potential hazards have been evaluated, has called for a committee to be established to define the hazards and to develop guidelines under which such research should be conducted. Part of the statement is given here.

*PAUL BERG, Chairman; DAVID BALTIMORE, HERBERT W. BOYER, STANLEY N. COHEN, RONALD W. DAVIS, DAVID S. HOGNESS, DANIEL NATHANS, RICHARD ROBLIN, JAMES D. WATSON, SHERMAN WEISSMAN, NORTON D. ZINDER.

Sciences of the National Research Council on this matter, propose the following recommendations:

"First, and most important, that until the potential hazards of such recombinant DNA molecules have been better

evaluated or until adequate methods are developed for preventing their spread, scientists throughout the world join with the members of this committee in voluntarily deferring the following types of experiments:

"Type I: Autonomously replicating bacterial plasmids that might result in the introduction of genetic determinants for antibiotic resistance or bacterial toxin formation into bacterial strains that do not presently carry such determinants, or construction of new bacterial plasmids containing combinations of resistance to clinically useful antibiotics unless plasmids containing such combinations of antibiotic resistance determinants already exist in nature.

"Type II: Linkage of all or segments of DNA from oncogenic or other animal viruses to autonomically replicating DNA elements such as bacterial plasmids or other viral DNAs. Such recombinant DNA molecules might more easily be disseminated to bacterial populations in humans and other species, and thus possibly increase the incidence of cancer or other diseases.

"Second, plans to link fragments of animal DNAs to bacterial plasmid DNA or bacteriophage DNA should be carefully weighed in light of the fact that many types of animal cell DNAs contain sequences common to RNA tumour viruses. Since joining of any foreign DNA to a DNA replication system creates new recombinant DNA molecules whose biological properties cannot be predicted with certainty, such experiments should not be undertaken lightly.

"Third, the Director of the National Institutes of Health is requested to give immediate consideration to establishing an advisory committee charged with (a) overseeing an experimental program to evaluate the potential biological and ecological hazards of the above types of recombinant DNA molecules; (b) developing procedures which will minimise the spread of such molecules within human and other populations, and (c) devising guidelines to be followed by investigators working with potentially hazardous recombinant DNA molecules.

"Fourth, an international meeting of involved scientists from throughout the world should be convened early in the coming year to review scientific progress in this area and to further discuss appropriate ways to deal with the potential biohazards of recombinant DNA molecules."

Wind of change at WMO

by John Gribbin

THE World Meteorological Organisation (WMO) has acted promptly on the statement made by Dr Henry Kissinger to the sixth special session of the United Nations General Assembly calling attention to the possible implications of climatic change for global food and population policies. It has been decided to establish a "Panel of Experts on Climatic Change" with the terms of reference:

- To review present WMO activities relating to climatic change and to make recommendations on any additional steps which may be necessary to integrate these activities into a coherent programme.
- To act as the focal point for WMO activities on climatic changes, trends and fluctuations, and their implications on the natural environment of mankind and on world food production.
- To advise on any necessary measures for the coordination of these activities.
- To advise on the policy implications for WMO of decisions of other international organisations relating to the impact of climatic changes.

Members of the panel have not yet been appointed, with the exception of the chairman Dr E. Süssenger, who is a member of the Executive Committee of WMO and head of the German meteorological service.

The panel will meet as soon as possible and is requested to prepare a report in time for consideration at the Seventh Congress of WMO, next year.

At present, the WMO is active in several areas of climatic research, although these are not coordinated. Perhaps best known is the work on the physical basis of climate and climate modelling, which is being carried out jointly with the International Council of Scientific Unions (ICSU) within the framework of the Global Atmospheric Research Programme (GARP). There are several international conferences in the pipeline including one on "Long-Term Climatic Fluctuations" to be held at the University of East Anglia next August; a spokesman for the Climatic Research Unit there said last week that many participants have already accepted invitations to attend.

Other aspects of climatic research are at present being studied under the aegis of WMO by their Commission for Atmospheric Sciences (CAS), and there is also a Commission for Special Applications of Meteorology and Climatology (CoSAMC) working group looking into problems of "Climatic Fluctuation and Man". It is perhaps hardly surprising that the president of the Commission for Agricultural

Meteorology (CAGM) is about to appoint a Rapporteur on climatic fluctuations and food production, or that the WMO is preparing papers relating to climatic fluctuations for presentation at the World Food Conference in Rome in November 1974. But clearly the time is certainly ripe for one panel to coordinate all these activities, and also to relate observations by the World Weather Watch (WWW) to the WMO studies. The new panel will include experts nominated by CAS, CoSAMC, CAGM, and the Joint Organising Committee of GARP.

Among the possibilities considered by the WMO Executive Committee were to designate either the CAS Working Group on the Physics of Climatic Fluctuations or the CoSAMC Working Group on Climatic Fluctuations and Man as a panel of the Executive Committee overseeing the WMO's climatic work. But the committee decided "in view of the desirability of formulating proposals . . . for consideration at the Seventh Congress, and bearing in mind the number of constituent bodies involved . . . to establish a [new] panel of experts" with the terms of reference as outlined above.

This panel will also be responsible for ensuring that WMO initiatives in this area are related to studies and work by other international bodies such as

UNESCO, the Food and Agricultural Organisation (FAO), the United Nations Environmental Programme (UNEP) and ICSU. A UNEP representative at the recent WMO Committee meeting confirmed the desire of UNEP to be associated with WMO in further studies of climatic change, and mentioned particularly the possibility of accelerating "those aspects of the WMO programme which would be of value for planning food production, especially in the developing regions". He suggested that statements of the statistical probabilities of successive years of unfavourable weather conditions would be particularly useful.

A spokesman for the British Meteorological Office welcomed this development, and said that the Met. Office accepts the WMO view that the future of our climate is an important topic for study. He pointed out that although climatic change has been receiving more attention lately, this has included publicity for some "shakily based views" ranging from claims that a new ice age is just around the corner to fears that the Earth is heading for a global desert situation. So it is certainly, in the view of the Met. Office, a good thing for an authoritative study of this kind to be carried out, and to put the various claims made about climatic change into perspective.

UK reactor choice

by Eleanor Lawrence

Winfrith SGHWR

At last the steam generating heavy water reactor (SGHWR) has been officially passed as the reactor choice for the next phase in the British nuclear power programme.

Announcing his decision in Parliament last week, Mr Eric Varley, Secretary of State for Energy, stressed five grounds on which he favoured the SGHWR.

- It will provide power reliably
- It can be ordered quickly
- The Nuclear Installations Inspec-

torate will give it safety clearance quickly

- It offers scope for British technology which should be exploited
- A 100-MW prototype at Winfrith has been operating successfully for six years and is designed to produce the operating conditions of a commercial unit.

Mr Varley plans to start with modest reactor units of around 600 MW and an initial ordering programme of not more than 4,000 MW over the next four years.

The government's decision runs counter to the strongly expressed wishes of the Central Electricity Generating Board (CEGB) in several respects. It wanted a large programme of a total of 36,000 MW using the American pressurised water reactors (PWRs).

Doubts on the safety of the PWR have been expressed both in the United States and in Britain, notably by Sir Alan Cottrell, former Chief Scientific Adviser to the Government. The Select Committee on Science and Technology was also opposed to the PWR. One of the main attractions of the SGHWR is undoubtedly its safety. Unlike the PWR there is no large pressure vessel, but a system of small-diameter pres-

sure tubes. These offer the 'leak-before-break' safety features which people feared might not occur with the pressure vessels of the PWR.

All the components of the SGHWR, except for the heavy water used as a moderator and perhaps the zirconium pressure tubes, can be made in Britain. Mr D. R. Smith, chief SGHWR engineer with the Nuclear Power Group, said that there would be few scaling-up problems except perhaps with the calandria tank surrounding the radioactive fuel elements. If the first orders were placed fairly quickly, as promised by Mr. Varley, building could start next year. Prospective sites include one at Torness in Scotland, for the South of Scotland Electricity Board (SSEB), and at Sizewell in Essex for the CEGB. Mr Smith thinks that the reactor could be completed.

The satisfactory Canadian experience with the similar CANDU reactor was probably a major factor in Mr Varley's decision. British experts who visited Canada recently were enthusiastic and close cooperation with the Canadians is expected. For the present, until the British programme is expanded, heavy water for the reactors will be imported from Canada. As soon as the SGHWR programme proves its worth, however, a British heavy water plant is envisaged, which would take advantage of the Canadian experience.

Money for old excavations

from Ian Caruana

THE Excavations Annual Reports, recently published by the British Department of the Environment (DOE) reveal that in at least one way archaeologists are failing to justify the additional cash they have been given in the past two years. In 1972 the annual government budget was in the region of £400,000; this year it has topped £1 million. One of archaeology's unceasing and justified complaints has been that the system of ministry grants for excavation never took account of the overriding need for publication, and financial austerity often made it a matter of necessity that an excavator spent almost all his time in the field just to make a living. It is, however, clear from the DOE's Reports that more money has not meant more publications. In fact while the number of digs financed directly by the DOE has risen steadily from under 80 in 1961 to over 200 in 1972 the number of reports published each year has remained more or less constant. The result is that there are now proportionally more excavations whose findings go unpublished than there were in 1961.

There is, however, one area above criticism—namely the permanent units

that are a developing feature of modern archaeology. (Their activities do not swell the DOE statistics because, although they receive a lot of government money, they also tap other sources and the DOE is quite happy to abdicate control in such cases.)

The Guildhall Museum's Department of Urban Archaeology in London is one such unit which, although set up only recently, has a good record. The results of two excavations from 1972, at Aldgate and Bush Lane House, were published last year. Four more reports are due out soon, one of which (dealing with work at the Customs House) took only five months to complete. Brian Hopley, the director, is responsible for a policy that ensures publication as quickly as possible. Each time a supervisor finishes a site he is immediately removed from the field and has to finish his site report before being given another site to run.

In addition the London unit is engaged in clearing the backlog of unpublished sites in the City. Through lack of resources, Peter Marsden (now Hopley's deputy) accumulated 70 sites which have so far yielded no published information about London's history. Now he faces a ten-year programme of publication—a feasible proposition inside a large unit with enough resources to back him up and to enable others to carry on with imminent excavation needs.

Salyut and after

from Verd Rich

ALTHOUGH the flight of Salyut 3 must inevitably be seen, in the short term, as a preparation for the joint Apollo-Soyuz programme of 1975, some of the experiments included seem directed at the longer term aim of establishing a permanent Earth-orbital station, as envisaged by Tsiolkovskii, and/or long term deep-space missions.

Accordingly, one of the major tasks of this mission is the testing of the life support systems, including the heat regulation system "in various regimes", and the regeneration of water from atmospheric condensation. The medical tests, effected with the multipurpose "Polinom-2M" apparatus, include the investigation of haemodynamics (the state of the circulation and the "rate of propagation of pulse waves along the arteries"), the ventilation of the lungs, and the collection of samples of exhaled air for subsequent laboratory analysis. It is intended to use the respiratory data to calculate the energy consumption in performing various tasks under weightless conditions—results which could be of considerable importance in planning the nutritional

requirements of a fully operational long term station or mission.

What these tasks are, either in the present mission or in future plans, is so far not entirely clear. The TASS reports, as ever, are tantalisingly brief, stating in this case, that the cosmonauts have "begun to test the possibility" of manufacturing hitherto unknown substances. A hint from the mission control station suggests that these may include steel "lighter than wood", and glass/metal alloys. In view of this brevity, speculation would seem fruitless at present.

Nevertheless, this type of experiment does suggest the Tsiolkovskii concept of a fully operational and self-maintaining orbital station, utilising the space "environment" for technology as well as research work. Although Tsiolkovskii's belief that the creation of such a station would be a necessary preliminary to any lunar or deep-space mission has been superseded by subsequent technology, Tsiolkovskii's name still exerts a considerable charismatic effect on the Soviet space planners. It is perhaps significant that, in a *Pravda* "background article" to the present flight, Candidate of Sciences N. Pisarenko of the Institute of Space Research of the Soviet Academy of

Sciences, discussing the radiation hazards of long term flights, states that primary cosmic radiation of galactic origin would, in the present state of the art, form a definite barrier to any manned Mars mission. He notes that "ways of overcoming this barrier" are being investigated, including "study of the self-shielding, restorative functions of the human organism and possibilities of intensifying them by the use of pharmacological preparations", as well as improvement of the shielding of the spaceship itself. For orbital stations, however, the hazard is considerably less, since according to estimates obtained from the data of Kosmos satellites, at the altitudes at which space stations operate (apogee of up to 500 km) cosmic radiation of solar origin is virtually absent and galactic primary cosmic radiation reduced by some three or four times in comparison with the deep-space value.

Both types of protection received an unexpectedly severe test when a solar flare occurred during the flight. According to TASS (July 15) "some physicists" wished to recall the cosmonauts. But it was decided that the Earth's magnetic field would protect them from the worst of the radiation, and they were instructed to use their antiradiation drugs.

MRC restructuring

by Peter Newmark

FROM September 1, 1974, substantial changes in the research boards that serve the Medical Research Council (MRC) will take effect. The Tropical Medicine Board is to be retained but both the Biological and Clinical Research Boards will be scrapped. In their place there will be three new ones—the Neurobiology and Mental Health Board, the Cell Biology and Disorders Board and the Physiological Systems and Disorders Board. It is the task of each board to advise the council on policy and to initiate and support research within its designated area of scientific objectives. In addition each board has the responsibility of maintaining research in and deciding the level of support needed for each of the disciplines or specialities that it encompasses.

As well as the four boards there is also to be an Environmental Medicine (Research Policy) Committee. This will cover all aspects of environmental, occupational and social medicine. The fact that these areas will include subjects (for example radiological protection) that are also of concern to the boards is recognised by ruling that the committee will allocate its funds as far as possible through the boards. Similarly each board will be able to use its funds for subjects covered by the committee.

The new boards seem to have a degree more power than previously. Whilst the council still carves the cake, it will be largely for the relevant board to allocate its own slice. One can hardly help noticing that the total number of board members has expanded much faster than the money available for them to share out (not forgetting that by 1975–76 about 25% of the MRC's grant-in-aid will be transferred to the Department of Health and Social Security and the Department of Employment to enable them to commission contract research to be carried out by the council).

The main objective behind the new MRC structure is clearly a step, or at least a nod, in the direction of Rothschild thinking. Instead of a horizontal structure dividing clinical from basic research each board is now vertically structured.

Erratum. In the article "Foetal research aborted in the United States" (*Nature*, July 12) the last sentence of paragraph 3 should have read "... research on fetuses *in vivo* has already produced some valuable conclusions and its banning is seen by some as shortsighted and ill-founded."

Lecturers lectured

FOUR lecturers at the Hebrew University in Jerusalem have been fired and another 12 transferred to new posts for poor teaching. Their achievements as teachers, as those of 220 colleagues, were evaluated on the basis of a survey carried out among several hundred science students at the Hebrew University by the Jerusalem-based Institute for Applied Social Research. The lecturers were graded on a five-point scale, with one point going to the worst and five to the best. Taken into account were student answers to questions such as: "Is the material usually presented in an interesting manner?"; "What attitude does the lecturer have towards relevant comments and questions?"; and "To what extent does the lecturer add to the information already available in textbooks?"

Analysis of the replies received has enabled the university to advise even relatively effective lecturers how they can overcome weak points. Professor Yitzhak Marcus, Chairman of the Curriculum Committee in the Natural Sciences Faculty of the Hebrew University, explains that the survey was not undertaken "to punish" lecturers.

New ways with fuels

by Allan Piper

IT was encouraging to hear original ideas given an airing recently in London where the Institute of Physics had arranged a meeting on "Novel physical methods of winning, burning and conserving fuels". Plants could be harnessed to produce hydrogen, said one participant, and another introduced the futuristic concept of mechanical miners. Most of the ideas are already well developed, but inevitably the 'establishment' found them 'uneconomical', and by implication not worth developing.

One topic was the potential use of solar energy through photosynthetic conversion to energy-rich plant material, which can then be converted by pyrolysis to alcohol, gas, oil and solid fuels. Dr O. D. Hall (Kings College, London), a botanist, pointed out that the amount of solar energy arriving at the Earth in three hours can meet the world's power demands for a year.

Photosynthesis in many economic crops is relatively inefficient. But in some other plants a more photosynthetic system, C₄, operates. Attempts to introduce the C₄ system into economic crops are in progress, together with a programme of plant breeding

aimed at developing plants which are more efficient and will produce specific desirable products. Hydrogen gas, a likely fuel for the future, can also be produced by photosynthesis, said Dr Hall. Under certain growing conditions algae can produce hydrogen, and model chloroplast-membrane systems have generated hydrogen in the laboratory.

If sunlight could be converted with an efficiency of 10% (compared with 0.2% naturally) only 1.5% of the land area of the United States would be needed to provide the total energy requirement of that country. Sunnier South Africa and Australia would need less still and even densely populated Britain would need to use only 9% of her land area.

Dr Hall stressed that an integrated approach using a variety of organisms, not only green plants, would be needed but that it would then be possible to harness all the sunlight between wavelengths of 400 and 900 nanometres.

Participants who found Dr Hall's ideas too revolutionary found little consolation in the next lecture. Professor M. W. Thring (Queen Mary College, London) said that much of the world's coal resources can never be tapped if we continue to use human miners. He introduced the concept of 'telechurics' hands at a distance. Already such automation has been used to service nuclear reactors and on the Moon. But the machines for mining coal would have to perform all the functions of a human miner. Professor Thring believes that expenditure of less than £100 million could develop such mechanical miners within 10 years; they would be operated by one worker from the safety of a control room.

But whatever we burn, we must learn to do it more efficiently. Professor F. Weinberg (Imperial College, London) explained that natural burning is a very inefficient process. Extremely low concentrations of combustible material in air—'lean mixtures'—cannot be burnt using conventional methods of combustion. But the efficiency of burning can be improved by preheating mixtures, said Professor Weinberg, thus allowing much leaner mixtures to be burnt. Useful supplies of energy could be extracted from waste gases, which at present are allowed to escape as pollutants into the atmosphere.

Professor Weinberg also discussed how electric fields could be used to regulate the behaviour of various pollutants within a flame, such as carbon or lead oxide smokes. Pollutants could then be induced to deposit in a particular position, on an electrode for instance, and particles could be manipulated, allowing control of their development and consumption in the combustion zone.

Business: multinationals in the news

by Roger Woodham

A COMMISSION on Multinational Corporations is called for in a recent report to the Economic and Social Council of the United Nations (UN) by a "group of eminent persons". The group was set up by the council to study the "impact of multinational corporations on development and on international relations", and during its deliberations it questioned some 46 witnesses including Mr. Ralph Nader, Mr. Altiero Spinelli (a member of the Commission of the European Communities) and Sir Val Duncan (Chairman of Rio Tinto Zinc).

The report makes it clear that the primary responsibility for the behaviour of multinationals rests with individual governments, which should be backed up by action at the international level to promote cooperation and harmonisation. The commission, the group envisages, will be made up of experts acting in their individual capacities and assisted by an information and research centre within the UN Secretariat. Some sort of general international agreement is the eventual goal (perhaps something like the General Agreement on Tariffs and Trade, GATT).

Particular concern is shown in the report about the effects of multinationals on developing countries, in many of which there is "widespread concern over foreign control of key sectors of the economy". The group thinks that host countries should clearly define the areas in which they are ready to accept foreign investment and that developing countries, especially, should be encouraged to retain ownership of their natural resources or control of the use of them. More

joint ventures between multinationals and individual governments may be the answer, with capital being made available by international financial institutions.

On the technological side, the report reiterates what others have said before, namely that the most up-to-date technology is not necessarily the most appropriate for a developing country. One of the group's suggestions is that host countries set up centralised negotiating machinery to deal with all aspects of proposals for foreign investment, the nature of the technology included.

The group thinks that the matter of multinational corporations needs to be discussed at least once a year by the Economic and Social Council. And in something of an understatement the report declares that "their activities are not *per se* geared to the goals of development".

● Hoechst UK, British subsidiary of the German chemical giant Farbwerke Hoechst, formally opened its new pharmaceutical laboratories at Milton Keynes last week. With a budget of £1 million a year the new laboratories are the latest in a series that Hoechst has been setting up throughout the world in the past six years—the others are in the United States, Japan and India. The emphasis at Milton Keynes is, however, to be on development, and the eventual full complement of 150 scientists will work on diagnostics and the development of possible new drugs rather than search for new chemical entities.

Hoechst has become particularly sensitive to the strong feelings that surround the use of animals for testing drugs because on two occasions last year a group calling itself the Band of Mercy attempted to burn down the laboratories as they were nearing com-

pletion. It failed, but the conspicuous presence of uniformed gentlemen from a private security company and the neatly rolled fire hoses near hydrants showed that the company is taking no further chances. Dr J. Coombes, head of Hoechst pharmaceutical research in Britain, made a special point of saying that "we would, of course, prefer to avoid the use of animals, with all their disadvantages, and we try to do this wherever we can, but in most cases it is just impossible." Safety tests on animals are required by law under the Medicines Act, he added.

First aid for the Aral Sea

from our Soviet Correspondent

UNTIL the grand, often publicised schemes for diverting the North Siberian Rivers Ob' and Yenesei so that instead of discharging into the Arctic they will irrigate the steppes of Central Asia, can at last be brought into effect, first aid measures are needed to save the Aral Sea.

This small inland sea, fed by the waters of the Amu-Darya and Syr-Darya was first hydrographically surveyed by a military expedition in 1848-9 (as part of the drive towards India), and has in the subsequent century and a quarter fallen some 3 m in level, because of the use of the rivers for irrigation.

The Aral basin contains more than half of the irrigated lands of the Soviet Union, 90% of the cotton crop, 40% of the rice and considerable quantities of fruit and vegetables. It is not, however, a lack of water in absolute terms that is the trouble, but a piecemeal use of what there is. During the spring floods the irrigated settlements are in considerable danger from flooding, and the only remedy at present is to divert the floodwaters to go to waste in the deserts.

The solution proposed is simple—a system of 13 dams to be built on the two rivers to contain the floodwater, distributing it for irrigation as required with the remainder being discharged into the sea. The surplus irrigation water will be collected and reused for irrigation and for leaching salts out of the soil, a method already in use in many of the Soviet Central Asian cotton farms.

The methods seem standard enough, but the publicity given to it and to its initiator, a certain Konstantin Rakitin (meriting a page and a half of a Novosti press release), would suggest perhaps that the prospect of a spectacular future solution—the diversion of the great Siberian rivers—has until now led to a neglect of the necessity for short term conventional measures.

New Hoechst laboratories

correspondence

Newton and Kepler

SIR,—The exchange of letters between J. Herivel and D. T. Whiteside (*Nature*, April 19, 634) arising from Herivel's review of my *Introduction to Newton's Principia* (*Nature*, 247, 163-4), hinges primarily on my alleged interpretation of an article by Whiteside (1964) and only secondarily on the substantive issue: Isaac Newton's possible knowledge of Kepler's law of areas before, 1676 or so, or even later.

When Whiteside's article appeared in 1964, I had already been engaged for several years in wholly independent research on the development of planetary astronomy before the *Principia* and on the source of Newton's knowledge of Kepler's laws. One of the central topics of my investigation had been the use of one of three then-current variant substitutes for (or approximations to) the area law—associated with the names of Bullialdus, Ward and Mercator. As I read through Newton's early manuscripts and book annotations, I was struck by the fact (it would have been impossible not to have been!) of the obvious and conspicuous lack of any early documentary reference by Newton himself to the law of areas—there is none dating from the period up to the famous exchange of letters between Hooke and Newton in 1679-80.

When Whiteside's brilliant article appeared, I temporarily laid aside my own book-length manuscript, but the postscript (page 137) to Whiteside's article refers to this work of mine. Accordingly, Herivel's remarks as to whether my opinion is or is not simply a correct interpretation of Whiteside's article may be seen to be irrelevant.

The substantive point at issue is not whether Newton may possibly have encountered the law of areas before 1676 (at which time he may very well have read the statement of the law in Mercator's treatise). It is rather whether at any time earlier than the end of his exchange of letters on motion with Hooke, in 1678-79, Newton consciously gave to this law any serious consideration as a possible basis of physical principles, or as an accurate (or most accurate) descriptive statement of the variations in planetary orbital speeds, or even as a major or significant element in considering planetary motions of the same order of

importance, say, as the elliptical orbits or the harmonic law. On the basis of ordinary canons of historical evidence, and to give my view the most accurate expression possible, the footnote in my *Introduction*, which is the occasion for these letters may be (in part) expanded and rewritten more fully so as to read:

"There is no documentary evidence that Newton was consciously aware of Kepler's law of areas (much less that he considered this law in any significant manner) prior to 1676, when he might well have encountered it in Mercator's *Institutionum Astronomicae Libri Duo*. At the end of his correspondence on motion with Hooke in 1679-80, or possibly soon thereafter, but at least by 1684, he used this law to solve the central problem of elliptical planetary motion, shown to result from the action of a centrally directed inverse-square force on a body with a component of linear inertial motion."

Yours faithfully,

I. BERNARD COHEN

Cambridge, Massachusetts

Family planning

SIR,—Poor parents in poor countries do not readily adopt family planning methods even when these are available to them, because they do not want to have small families. They want large families for various reasons, many of which are economic; children provide free labour on family farms, security in old age and so on. Economic motivations can be changed by economic means. Under present circumstances a substantial reduction in the rate of population growth appears to depend on widespread economic improvement: but in many developing countries widespread economic improvement does not seem feasible unless there is a substantial reduction in the rate of population growth.

The problems are familiar, but they may not be insoluble. In many parts of the world the parents' desire for large families seems to represent to a great extent a desire for sons. If such parents could choose to have sons rather than daughters they would probably do so; if a cheap and simple method existed which increased the chances of having sons rather than

daughters, it would probably be readily adopted. The total number of children needed in order to obtain any given number of sons would be reduced. And in the long term, the shortage of women of child-bearing age would lead to a further reduction in the birth rate.

Human sperm bearing X and Y chromosomes can be separated *in vitro* on the basis of their differential motility. Y-sperm, which are male-determining, have a greater ability to penetrate an interface between a less viscous and a more viscous fluid and also out-distance X-sperm by swimming faster in a fluid of relatively high density and viscosity¹. It is not inconceivable that some method could be devised whereby a suitable viscous solution could be introduced (for example within a capsule) into the female genital tract in such a way that after sexual intercourse the X-sperm were selectively retarded and the chances of conceiving a male child were increased.

The idea that the ability of parents to choose to have sons rather than daughters could lead to a substantial reduction in the birth rate, especially in countries with high rates of population growth, has been proposed before²; the recent findings on differential sperm motility suggest that this idea should now be taken seriously.

If a suitable method could be developed and if it were adopted on a wide scale, the increased proportion of males in the population would undoubtedly create new problems, some of which are easy to imagine. But what are the imaginable alternatives? In India, for example, in spite of a well-established, government-sponsored family planning organisation and mass sterilisation programme, the population is now increasing by one million every twenty-five days.

Yours faithfully,

A. R. SHELDRAKE

news and views

What does BL Lac?

MANY extragalactic objects—the nuclei of some galaxies, quasistellar objects, N systems and objects of the BL Lacerta type—contain very small components which vary in optical light, and in radio flux. The variations take place on time scales which vary from days or weeks up to many years. Objects with a wide range of redshifts are involved, and of course until recently no lines had been identified in objects of the BL Lac type.

Radio astronomers using very long baseline interferometers have measured very small angular sizes 10^{-3} – 10^{-4} arc second in some sources, and apparent changes in angular structure have been seen in several of them. The time variations which occur either in flux or in angular size, when interpreted using distances obtained from redshifts (that is on the cosmological assumption), have led to various apparent difficulties in interpretation.

The very small sizes set by the light travel time and the very large optical fluxes set by the large redshifts lead to immense photon fluxes, and apparent contradictions involved in the interaction of the photons with the electrons which must generate them. This problem, originally raised by Hoyle, Burbidge and Sargent in 1966, has been argued about, skirted around and sometimes denied.

In cases where one has angular size measurements and radio spectra which turn over, suggesting synchrotron self-absorption, detailed calculations can be made (see for example Jones, O'Dell, Stein and Burbidge *Astrophys. J.*, **188**, 353; 1974). If flux variations in such radio sources are explained in terms of a simple expanding cloud model, it is found that for all sources with large cosmological redshifts and rapid variations the expansion must be highly relativistic. This means that enormous energies of the order 10^{50} erg or greater are released in frequent outbursts, part of the energy being associated with relativistic expansion against the surrounding medium. Because of the short time scales the cumulative energy problem is very severe.

In sources in which angular sizes seem to have varied, the observations were first thought to indicate relativistic motion of components—separations of doubles, and so on—at relativistic speed. Thus, there was talk of apparent superlight velocities. By now the difficulty and ambiguities of interpretation of the radio data have led some people to discount models of this type, and models in which it is supposed that several small spatially separated components are varying independently are now in vogue. These too have their difficulties.

All of these apparent problems raised by such sources stem, however, from the great distances implied by the redshifts. For comparatively close objects, such as the radio galaxy NGC1275, low and entirely reasonable optical and infrared radiation densities, non-relativistic motions and lower energies are required. Thus, for some time, either the unpopular view that the redshifts are not measures of distance, or the notion that nobody really understands the physics of the sources has been the basis of the two approaches taken by students of the subject.

Until recently the BL Lac objects which show very rapid flux variations and all of the other continuum energy properties of, for example, QSOs, could not be brought into the debate because no redshifts had been measured.

Now within the space of three months redshifts for two of them, BL Lac itself (Oke and Gunn, *Astrophys. J. Lett.*, **189**, L5; 1974) and PKS0735+178 (Carswell, Strittmatter, Williams, Kinman and Serkowski, *ibid.*, **190**, L101; 1974) have been published. What is one to make of them? The strongest claims have been made for BL Lac. Full publicity has been accorded to the view of Oke and Gunn that BL Lac is a QSO embedded in an elliptical galaxy with a redshift $z=0.07$. Discounting for a moment the fact that the paper and the news releases (which many scientists have read more carefully than the paper itself) appeared on April Fools' Day, how seriously should one take this claim? Earlier arguments of different kinds by Adams (*Astrophys. J.*, **188**, 463; 1974) and by Wlérick, Michet and Lelièvre (*C.r. hebdomadaire Acad. Sci., Paris*, **278**, 245; 1974) in which it has tacitly been assumed that a normal galaxy does underly the nonthermal object, have led to distance estimates which range from 130 Mpc ($z=0.022$) to 420 Mpc ($z=0.07$). The Oke-Gunn result rests on scanner observations of the outer parts of the object and it is claimed that weak absorption features, not all of which are identified, are those expected from stars in a normal elliptical galaxy. The problem is that the observation is very difficult, the features are weak and the reality of some, and perhaps all of the absorption lines, is in doubt.

What can be learnt from the other BL Lac object PKS0735+178? In this investigation the authors have made no claim to have discovered a stellar component. The redshift rests on two comparatively sharp absorption features which they attribute to Mg II, based on the separation between the two components of the doublet. These are not likely to be due to stars, otherwise the two components would be smeared into one broader line. The absorptions are more like those arising in gas clouds which are often seen in high-redshift QSOs. The object is variable in optical light and in polarisation on time scales less than a month.

Thus, on the face of it, these first two BL Lac objects in which spectroscopic features have been found seem to be different. One may have its source in a normal galaxy with a lineless QSO (a contradiction in terms of the original definition) embedded in it. The other, as far as is known, is a nonthermal continuum object with QSO-like absorption in it.

Should these interpretations be taken seriously? The answer is that one should be exceedingly cautious at this point. The most important thing is to check the BL Lac observations using independent and, if possible, superior equipment. It would not be at all surprising, despite the ballyhoo and the claims, if they did not survive. It is interesting to see how easily theoreticians tend to accept this result at face value, when compared with the way they looked sceptically at the original gravitational wave results.

What bearing do these results have on the problems mentioned earlier? If BL Lac is at a distance of 420 Mpc, then as Oke and Gunn point out, the luminosity and rapid variations of the central object give rise to all of the apparent difficulties associated with understanding the radiation properties of the large-redshift QSOs. The same can be said for PKS0735+178 which has an even larger redshift ($z=0.424$). At the same time the results do not provide direct evidence against the possibility of noncosmological redshifts. If it is supposed that a QSO is embedded in a galaxy, it must be proved that each component has the

same redshift if the noncosmological hypothesis is to be disproved. In BL Lac only the redshift of the outer part has been observed. The centre is excluded. This argument is the converse of that used by Kristian (*Astrophys. J. Lett.*,

179, L16; 1973) who, having observed QSOs whose redshifts had been measured and which have fuzz around their images, assumed, without proof, that these were galaxies.
GEOFFREY BURBIDGE

Three abundance classes of messenger RNA

GENE expression has both a quantitative and a qualitative component. It is important to know not only which genes are expressed but also how many transcripts of each are present. On page 199 of this issue of *Nature* Bishop, Morton, Rosbash and Richardson show by two independent methods that in HeLa cells approximately 1% of the single copy DNA, enough to code for about 35,000 different average-sized proteins, is transcribed into cytoplasmic messenger RNA which may be isolated by affinity chromatography on oligo (dT) cellulose. These mRNA molecules are present in three distinct frequency classes. About one fifth of them are transcribed from a very few (about 17) sequences but are present in great abundance (about 10^4 copies each per cell). One half of the mRNA is derived from a very large number (about 35,000) of different genes but individual mRNA sequences are present at low concentration (about 10 copies per cell). The remainder of the message population derives from an intermediate number of genes (about 350) and each is represented by approximately 450 copies per cell.

The kinds of experiment from which these numbers are derived involve purification of cytoplasmic mRNA by affinity chromatography on oligo (dT) cellulose. Although this method does not give a total message preparation (for instance histone mRNA will not be present), it seems likely that it will contain the bulk of the mRNA. Highly radioactive DNA complementary to the purified mRNA (cDNA) is synthesised by viral reverse transcriptase for use as a probe in nucleic acid hybridisation reactions. Bishop *et al.* performed two types of hybridisation reaction with their antimesage cDNA—one using total DNA in excess and one using purified mRNA in excess. The DNA-driven reaction shows that cDNA prepared from total cytoplasmic message hybridises to both repetitive (about 10%) and non-repetitive (about 70%) components. A control using purified radioactive HeLa single copy DNA instead of cDNA defined a rate constant for the renaturation of HeLa unique sequence DNA which is nearly identical to the rate constant determined for the second transition of the cDNA reaction, providing convincing evidence that cDNA is reacting with unique sequences. These results suggest that most of HeLa cytoplasmic message is transcribed from unique DNA but a small fraction (about 15%) derives from a class of intermediate repetitive sequences.

The rate of the RNA-driven hybridisation reaction between cDNA and mRNA template in excess is determined by the relative concentration as well as by the absolute number of different mRNAs in the total preparation. If all mRNAs are at equal concentrations then the reaction will have a single transition with a rate constant determined by the number of reacting species. But if some RNAs are present in greater amounts than others they will react faster and show up as an early transition or step in the progress curve of the reaction. The actual curve relating extent of cDNA hybridised to the R_{ot} (product of initial mRNA concentration and time) shows three such transitions suggesting at least three major frequency classes in the mRNA population. In order to interpret these curves, a kinetic standard of known sequence reiteration frequency and molecular weight is required. Reaction between excess rabbit haemoglobin α chain mRNA or a mixture of α and β

chain mRNA and homologous cDNA provides such a standard. A further requirement for estimating numbers of gene transcripts is a measurement of the number-average molecular weight of HeLa mRNA which was determined at 600,000 daltons—about three times the molecular weight of haemoglobin α chain mRNA. Dividing the observed $R_{ot/2}$ for each transition by the $R_{ot/2}$ of the kinetic standard corrected for the difference in molecular weights gives an estimate of the number of gene sequences contributing transcripts to that frequency class.

These calculations are necessarily approximate since they rely on unverified assumptions such as the general applicability of a number-average molecular weight determined for the total mRNA population to different subsets of that population and uncertainty about the contribution of repetitive gene transcripts to each of the three frequency classes. Furthermore, it is not clear at present whether all poly(A)-containing RNA is transcribed by reverse transcriptase with equal efficiency. In the worst case an entire frequency class might not be transcribed at all and clearly would not be detected by hybridisation. If on the other hand there were only slight variations in transcription efficiency this would not matter particularly since the rate of hybridisation depends on the concentration of cold driver, either RNA or DNA, and not on the concentration of cDNA. What might be mistaken though would be the relative amount each frequency class contributes to the total population since these are determined by the plateau values and not by the reaction rate.

A third type of experiment using purified ^3H -labelled single copy HeLa DNA instead of cDNA as the probe in an mRNA excess reaction allowed a totally independent estimate of the proportion of the genome transcribed to give cytoplasmic message. Both the cDNA and the purified single copy reactions led to the conclusion that about 1% of the unique sequence is represented in mRNA and allow some weight to be attached to this estimate.

This work represents a significant advance in the understanding of both gene expression and in the likely numbers of different sequences involved. But many intriguing questions remain. Do HeLa cells really synthesise 35,000 different proteins or do some unique sequence transcripts not code for proteins? Are HeLa cells expressing their maximum genetic potential or is even this large amount of information only a small part of their true capacity. In this regard it is noteworthy that a *Drosophila* cell line seems to express an order of magnitude fewer sequences (4,000) in cytoplasmic mRNA and it may well turn out that HeLa cells are atypical in the amount of information found in cytoplasmic message. The existence of three frequency classes of mRNA, most of which derive from single copy DNA sequences, clearly focuses attention on the differential control of mRNA synthesis and degradation. It may be that differential rates of synthesis are responsible for variation in the steady state level of particular mRNAs but equally likely at present are differential rates of degradation, for which there is already evidence in HeLa cells. Finally, it is clear that a cell contains different abundance classes of protein and it would be interesting to know to what extent this reflects the frequency classes in mRNA.

PETER J. FORD

DNA of hepatitis B virus

SIGNIFICANT advances in research on hepatitis B virus have been made recently by groups at several centres in the United States. Experiments by Hirschman and his colleagues (*Lancet*, i, 1099; 1971) first indicated the presence of a DNA polymerase activity in association with hepatitis B antigen. Crude pellets of antigen, obtained by high speed centrifugation of sera from a few patients with clinical and histological evidence of hepatitis, were found by electron microscopy to consist largely of the small pleomorphic 16–25 nm spherical particles of hepatitis B antigen, although the larger 42 nm spherical particles and tubular forms of varying lengths were also found. These preparations were found to stimulate the incorporation of tritiated dTTP into an acid-insoluble product in the presence of all four deoxynucleoside triphosphates, albeit at a low level. The reaction was considered to be dependent on an endogenous RNA template or primer since pretreatment of the samples with RNase abolished their activity. The reaction was, however, stimulated by the addition of poly (dAT) and not by poly (rA)-oligo (dT), as are the known RNA-dependent DNA polymerases.

Kaplan *et al.*, (*J. Virol.*, 12, 995; 1973) have reported the finding of a DNA polymerase activity in plasmas positive for hepatitis B antigen, selected because of their relative rich content of the 42 nm double-shelled spheroidal form of the antigen. DNA polymerase activity was associated with the core component of the 42 nm particle after removal of the outer surface antigen coat by treatment with the non-ionic detergent Nonidet-P40 (NP 40). Surprisingly the enzyme seems to function in the absence of any exogenous template. The incorporation of tritiated dTTP was dependent on the presence of all four deoxynucleoside triphosphates and magnesium ions, suggesting that a DNA or RNA template within the core probably directs the synthesis of DNA. The properties of the enzyme product were further assessed using ³H-dTTP as the trace label. Digestion with pronase followed by phenol extraction resulted in the appearance of about 20% of the acid-precipitable label in the aqueous phase. This extract possessed a buoyant density of 1.71 g cm⁻³ and a sedimentation coefficient of 110S, which was reduced to 15S after incubation with sodium dodecyl sulphate. Rate zonal centrifugation confirmed the close association of the polymerase with a proportion of the 42 nm antigen particles, within which the template molecule lies in a protected state. No enzymatic activity was found in highly purified small (16–25 nm) hepatitis B surface antigen particles. Kaplan *et al.* concluded that if the DNA polymerase is a virion enzyme and if the reaction is DNA dependent (as was suggested by inhibition of the reaction by actinomycin D and daunomycin), then the enzyme would be unique because similar virion enzymes have not been described so far.

Kaplan and his colleagues (*Nature*, 249, 762; 1974) went on to study hepatitis B DNA polymerase activity during the course of post-transfusion hepatitis. The polymerase activity was detected later than hepatitis B surface antigen but before serum transaminase levels were elevated so it was concluded that polymerase activity was related to viraemia and not to virus-induced liver damage. Krugman *et al.* (*New Engl. J. Med.*, 290, 1331; 1974) also concluded, after the examination of serial samples of serum from volunteers exposed to the MS-2 strain of hepatitis B virus, that DNA polymerase activity seems to identify the period of peak replication of hepatitis B virus.

Further observations on the nature of the polymerase and the product of its reaction were reported recently by Robinson of Stanford University School of Medicine at a seminar held at the London School of Hygiene and

Tropical Medicine (full details will be published in the *Journal of Virology*). Hepatitis B surface antibody removed the enzyme from the reaction mixture in the absence of the detergent NP 40, but in the presence of NP 40, which exposes the core, the enzymatic activity was found in the supernatant and could only be precipitated by the core antibody and not by the surface antibody. As expected from these results, the addition of purified 16–25 nm surface antigen particles effectively competed with the surface antibody and blocked the precipitation of the enzyme-containing particles in the absence of the detergent, but after treatment with NP 40 the purified small particles did not block the precipitation of the core by the core antibody. The DNA polymerase activity, after treatment of the antigen preparations with the detergent, was found at a closely similar position in a sucrose gradient as the 28 nm core particles. The 110S structure was found to be associated with the core by immunoprecipitation with hepatitis B core antibody. Advantage was taken of these two latter observations to provide a sensitive test for core antibody in sera of patients and carriers by using the DNA polymerase and the radioisotope-labelled DNA reaction product as markers for the core.

The initial finding that the DNA polymerase activity, associated with the core particle, does not require added DNA or RNA implies that the core contains nucleic acid which served as a primer template for the reaction. A major advance with this work has been the observation by electron microscopy of circular DNA molecules by shadow casting. Briefly, the procedure involved concentration of the 42 nm hepatitis B antigen particle by centrifugation followed by purification by repeated equilibrium centrifugation in sucrose density gradients. The preparations were exposed to DNase in order to eliminate free DNA. After treatment with the detergent NP 40 the cores were isolated by rate zonal sedimentation and treated again with DNase. After further centrifugation the core pellets were disrupted with sodium dodecyl sulphate to release any nucleic acid. Incubation with DNase I before electron microscopy removed all of the circular molecules, whereas RNase had little effect. The smooth, open configuration of the molecules suggests that they are double stranded and additional molecules of single stranded nucleic acid were not found after spreading in formamide.

In other experiments, dissociation of the core particles with lithium thiocyanate again revealed small circular nucleic acid molecules. The circular structures were not supercoiled and Robinson suggests that this appearance may be due to an open circular conformation with a nick in one of the two strands. Size distribution analysis give a mean length of the circular molecule of 0.78 μ m corresponding to an estimated molecular weight of the DNA of about 1.6×10^6 . This is smaller than double stranded DNA found in any known 'complete' virus and it is similar in molecular weight to adeno-associated virus. The thermal denaturation kinetics of the isolated DNA confirmed its double stranded nature and gave a result consistent with a G:C content of 48 to 49%.

This is a somewhat unexpected finding in view of the similarity to the base composition of mammalian DNA, and if this is representative of part or the whole of hepatitis B virus genome it is more consistent with those viruses possessing the ability to integrate their own genome into that of their host. Furthermore, it is difficult to envisage that this molecule is capable of coding for more than five or six proteins and would therefore almost certainly not contain sufficient information to satisfy the requirements both for active virus replication and the apparent complexity of the surface determinants on the particles associated with hepatitis B antigen. It is also difficult to imagine the active association of the enzyme and template within the confines of the core of the 42 nm particle. The

possibility of their segregation as components of different morphological forms, in a manner perhaps similar to the Fraenkel-Conrat covirus model for some plant viruses which require two or more particles to produce infection (a concept which was extrapolated to human hepatitis type B (Zuckerman, *Vox Sang.*, **19**, 304; 1970)) cannot yet be ruled out. There is also the possibility that the circular DNA is derived from a defective virus, and infectious particles with larger DNA molecules, which have not yet been detected, might be present. Alternatively, a helper virus might be required for replication (Kassanis, *J. gen. Microbiol.*, **27**, 477; 1962) and, although a second or helper virus has not yet been identified, such models for hepatitis have been proposed (Zuckerman *et al.*, *Nature*, **214**, 606; 1967).

The findings just reported by Robinson clearly represent one of the most significant steps forward in hepatitis research, but further work is required to establish conclusively the nature of the DNA polymerase template, to identify the enzyme as viral and not host specific and to clarify some of the other puzzling characteristics of the intriguing hepatitis B virus.

ARIE J. ZUCKERMAN
COLIN R. HOWARD

r and *K* rodents in Costa Rica

from our Animal Ecology Correspondent

THE demographic strategy employed by a species population is a function of, and is dependent on, the ecological complexion of its environment. This affirmation of the status of the population led MacArthur and Wilson (*The Theory of Island Biogeography*, Princeton University Press, 1967) to underscore and draw attention to the significance of *r* and *K* selection. In seasonally fluctuating environments it is argued that populations will seldom achieve a density corresponding to the carrying capacity (*K*) and so intra-specific competition for food and other resources will be low. Natural selection will favour those genotypes that produce large litters of early maturing young. In environments that lack a marked seasonal boost in productivity, that is, with *K* remaining constant, intraspecific competition will always be strong. Selection under these conditions (*r*) favours species that produce small litters of highly competitive young. Additionally one might expect that individual longevity is increased in non-seasonal environments along with other factors which serve to heighten survivorship such as deferment of sexual maturity. Thus *r* selection represents selection for a rapid energetic turnover

and *K* selection represents selection for efficiency of exploitation (Pianka, *Am. Nat.*, **104**, 592; 1970).

In general the concept is important for ecologists concerned with the artificial control of rodent populations. Microtines from the temperate regions are typified by high reproductive output (5 litters per year; 5-8 young per litter), low survival (2-4 months) and high population densities (up to 1,000 per hectare). Heteromyids from the arid regions of the New World have low reproductive outputs (2-3 litters per year; about 2.5 young per litter), high survival (up to 5 years in the field) and low population densities (about 0.5-5.0 per hectare). At this level the concept seems to hold up well. What demographic strategies are adopted by two closely related species of rodent which occupy seasonal and nonseasonal environments respectively within the same biogeographical region? A recent study by Fleming may help to answer this question (*Ecology*, **55**, 493; 1974).

Two study sites in Costa Rica, one a dry, seasonal tropical forest, the other a wet nonseasonal tropical forest were chosen. They were separated by about 130 km. The terms seasonal and non-seasonal were used after sufficient vegetational and climatic studies had shown there to be a distinct presence and absence respectively of an annual boost in primary productivity. Fleming chose to study the population dynamics of two closely related species of heteromyid rodents, *Heteromys desmarestianus* and *Liomys salvini*. In Costa Rica *Liomys* occurs in the seasonal dry forests and *Heteromys* in the nonseasonal wet forests. Although Fleming admits that a single comparison between two species can, at best, give only weak support to a general concept, the paucity of field observations demands that a second look is taken at what data there are. *Liomys* matures earlier than *Heteromys* (3-4 months as against 8 months) and has slightly larger litters (3.8 as against 3.1). Juvenile survival is higher and mean longevity slightly greater in *Heteromys*. *Liomys* juveniles and adults weigh significantly less than comparably aged *Heteromys*.

The field study lasted only 1 year with an additional month's study almost a year later. These observations must therefore be treated with caution. The effects of other ecological factors, such as predation pressure, while their existence was noted, were not measured. Nevertheless it seems that Fleming has provided a *prima facie* field example in support of the concept made all the better by it involving two closely related species (normally regarded as *K*-selected species) in adjacent, but ecologically distinct, habitats.

R to T with IHP

from a Correspondent

FROM a large number of interesting papers on structural and functional aspects of haemoglobin, a series of three long reports on the "Influence of Globin Structure on the State of the Heme" (*Biochemistry*, **13**, 2163, 2174, 2187; 1974) commends itself for attention. The series is noteworthy in carrying the names of ten authors from six different laboratories in the United Kingdom, the United States and Nigeria, and makes simultaneous use of a wide range of techniques.

In part 1 on human deoxy-Hb, Perutz, Ladner, Simon and Ho have used two modified haemoglobins and a mutant, all of which can be made to remain in the R (oxy) quaternary state when fully deoxygenated, and switch to the T (deoxy) state by addition of inositol hexaphosphate (IHP). By using such haemoglobin species, the effect of the R → T transition on the 5-coordinated ferrous haems can be studied in the absence of any dissociation of ligands. In the fully deoxygenated but R state, des-Arg(β -141)-Hb, NES-des-Arg(α -141)-Hb and Hb-Kempsey (β -99 Asp → Asn) all have electronic absorption spectra, ultraviolet circular dichroism and paramagnetically shifted proton NMR (nuclear magnetic resonance) spectra which differ markedly from those of normal deoxy Hb-A and resemble those of summed free deoxy α and β subunits. Addition of IHP switches them to the T state with electronic and NMR spectra like those of deoxy Hb-A. The switch also gives rise to small absorption and CD spectral changes that are most probably due to structural changes at the $\alpha_1\beta_2$ contact area affecting the trp (β -137) and tyr (α -142) residues.

Part 2, by Perutz, Fersht, Simon and Roberts, on allosteric transitions in methaemoglobin, makes use of optical, kinetic and NMR procedures to demonstrate that binding of IHP shifts the

Movement of SH on transition of haem to lower spin

Effect of changes in spin state of the haem on the F helix and on the freedom of the sulphhydryl group of cysteine-93 β to react with ligands. Quaternary R structure (from *Biochemistry*, **13**, 2182; 1974).

allosteric equilibrium of high-spin methaemoglobin derivatives (aquo-, fluoro-) in favour of the T (deoxy) state. The reduced reactivity of the β -93 sulphhydryl groups is also comparable with that observed for deoxy as compared with oxy-haemoglobin. IHP seems to bind to the same site in met- as in deoxy-haemoglobin, between the terminal amino groups of the β chains. Smaller changes in the UV spectra and SH group reactivities are induced in low-spin methaemoglobin derivatives (azido-, cyano-) by IHP without the sign reversal in the CD spectrum at 287 nm associated with the R \rightarrow T transition of deoxy-haemoglobin. Similarly, the NMR studies show that for the high-spin derivatives IHP causes larger changes in the ring-current-shifted resonances of some aromatic residues than it does for the low-spin derivatives. Taken as a whole, these observations indicate that solutions of high-spin methaemoglobin derivatives contain both R and T forms in equilibrium, with the R form favoured by high pH, and the T form by low pH and the binding of organic phosphates. This scheme can account qualitatively for the pH dependence of the redox equilibrium of haemoglobin and its sensitivity to chemical modification, and there is an interesting interpretation of the redox data in allosteric terms.

Part 3, by Perutz, Heidner, Ladner, Beetlestone and Slade, considers changes in the visible and near-IR absorption spectra, paramagnetic susceptibility, paramagnetically-shifted proton-NMR and electron spin resonances induced in high- and low-spin methaemoglobin derivatives by IHP, and relates them ultimately to changes in the distances between the iron atom and its ligands. The increased Fe-N bond distances observed in the T structure implies that the globin exercises tension on the haem which pulls the iron atoms further from the porphyrin ring plane, opposing the transition to the low-spin state needed for combination with oxygen and hence reducing the oxygen affinity. Finally, since haem-haem interaction is observed only when a change in quaternary structure accompanies reaction with ligands, the present findings imply that it is coupled to a change in tension at the haem, transmitted by a change in quaternary structure of the globin. This brings the discussion back to globin, which is the starting point of the series. It should perhaps be added that comprehension of the large amount of diverse experimental data is greatly helped by some summary tables and figures *en route* which summarise particular conclusions and implications reached during the course of the tightly argued discussion.

Mitotic spindle assembly *in vitro*

from a Correspondent

Two main approaches have been taken in studies of the mitotic spindle. Measurements of the birefringence of the spindle in intact cells by Inoue and others have suggested that the fibrous components of the spindle are in dynamic equilibrium with subunits. The birefringence of the spindle is lost when living cells are exposed to cold, high hydrostatic pressures and to colchicine and other antimitotic alkaloids. These agents are thought to depolymerise reversibly the microtubules of the spindle fibres and so prevent chromosome movement in intact cells. The other approach has been to isolate the intact mitotic apparatus, usually in the presence of stabilising agents such as glycols. This procedure has provided useful information about the chemistry of the mitotic apparatus but not how it works, because reversible assembly and disassembly have not been achieved with spindles so prepared.

Three groups of investigators have now reported the preparation of mitotic spindles which can be made to increase or decrease in size by appropriate treatment of the subcellular materials. The spindles are isolated in the presence of added rat brain tubulin and agents which chelate calcium, thereby preventing the disassembly of spindle microtubules. Cande, Snyder, Smith, Summers and McIntosh (*Proc. natn. Acad. Sci. U.S.A.*, **71**, 1559-1563; 1974) lysed rat kangaroo cells with the detergent Triton X-100 into a solution of polymerisable rat brain tubulin and obtained spindles which lose and gain birefringence when cooled and warmed; the spindles can move anaphase chromosomes to the opposite ends of cell preparations. Early anaphase cells lysed into buffers containing polyethylene glycol and nucleotide triphosphates showed spindle elongation and chromosome movement in the absence of added tubulin subunits. The authors conclude that although spindle growth requires microtubule polymerisation, anaphase motions do not.

Rebhun, Rosenbaum, Lefebvre and Smith (*Nature*, **249**, 113-115; 1974) report that spindles isolated from eggs of the surf clam (*Spisula*) cooled and then warmed with chick brain tubulin showed increased birefringence in the form of fibres similar in distribution to the mitotic apparatus of living cells. Sometimes such artificially polymerised spindles were larger than normal spindles. The isolated spindles increased in length but did not shorten and were stable to dilution of tubulin. It seems that they can assemble tubulin more

readily than they can break down the assembled units.

Inoue, Borisy and Kiehart (*J. Cell Biol.*, **62**, 175-184; 1974) found that tubulin purified from porcine brain augmented the birefringence of *Chaetopterus* spindles. The cells were lysed in a hypotonic calcium-chelating solution, and in the presence of tubulin, spindles and asters grew considerably larger than those in intact cells. The isolated augmented spindles depolymerised rapidly at 6° C, and birefringence was slowly recovered upon return to 23° C. The birefringence of the spindles also decreased in the presence of 2.5 mM calcium but not on dilution of tubulin or in the presence of colchicine or colcemid.

The results represent a useful advance in knowledge of the mitotic apparatus. They show that the conditions required for polymerisation of isolated spindle microtubules are similar to those defined by Weisenberg and others for tubulin from various sources, including surf clam eggs. The response of the isolated spindles to temperature reflect those observed in intact cells, but other responses, such as those to colchicine do not. Disassembly does not follow dilution of tubulins, so that a simple equilibrium between the protein subunits and spindle microtubules is unlikely to explain fully the behaviour of the spindle. Perhaps improvements in isolation technique will produce spindles that perform more like those in intact cells. Since exogenous enzymes, cofactors and inhibitors can gain access to the isolated spindles, it should be possible to analyse their role in spindle formation and disassembly. The spindle, however, is itself likely to contain a complex mixture of enzymes and other constituents, so that the analysis will not be straightforward.

Gibbons and others have found how useful sperm tail preparations made accessible to exogenous agents by detergents can be in analysing flagellar movement, and similar analyses should be possible with isolated spindles. It would be of great interest to know whether spindle assembly or disassembly depends on reversible polymerisation of tubulin and whether the presence of dynein, actin or some other contractile protein is required for chromosome movement. Apparently low calcium is necessary for assembly, as well as phosphorylation of GDP tightly bound to tubulin. Jacobs at King's College London, has recently been studying a transphosphorylase associated with tubulin, but separable from it, which seems to be involved in the assembly process. Among the many possible systems involved in the control of spindle assembly and action are the concentration of calcium and level of transphosphorylase activity.

The commonplace and unexpected from high energy physicists

from David J. Miller

LAST year's wonder has become this year's commonplace. On July 1, the opening day of the International Conference on High Energy Physics at Imperial College, London, five separate new pieces of evidence for neutral weak currents were reported. Moreover, the two groups who had published previously reported greatly improved statistics (see *Nature*, **245**, 119; 1973 and **249**, 211; 1974 for discussions of the first neutral-current result, from the Gargamelle bubble chamber at CERN, Geneva and of the early Harvard/Fermi Laboratory results).

The most striking of the new pieces of data comes from a group at the California Institute of Technology, which used an array of counters, spark chambers and magnets in a neutrino beam at the Fermi National Accelerator Laboratory (FNAL). The momentum of their neutrino beam is known better than in the first Harvard-FNAL experiment, and they have a clearer technique for identifying events without fast muons. Their ratio for muonless neutrino events (neutral-current mode) to events with a muon (charged-current mode) is 0.22 to 1. With an antineutrino beam the equivalent ratio is 0.33 to 1. Although their neutrino beam momenta are around 45 GeV/c or 120 GeV/c, compared with around 1 to 10 GeV/c in Gargamelle, this neutrino ratio is very close to the latest Gargamelle figure, and the antineutrino ratio is not alarmingly different, considering the greater uncertainties involved in small antineutrino statistics. A collaboration of 'East Coast' university groups, working at the 29 GeV/c Brookhaven accelerator near New York, has also seen a clear neutral-current signal in a spark chamber experiment.

Two groups reported the observation of neutral-current events with all the final-state particles identified. In Gargamelle and in the big spark chamber arrays, this has been difficult, since the neutrinos interact with the protons or neutrons of a heavy nucleus. At the Argonne Laboratory, near Chicago, a group from Argonne, Concordia College and Purdue University has used the 12-foot bubble chamber, filled with liquid hydrogen or deuterium, to identify about 14 events in which a neutrino struck a single proton (or a neutron in deuterium). The final state in each of these events contained a positive or a neutral pion, plus a recoil neutron or proton (and also a visible 'spectator' proton, in deuterium). As

with all neutral-current experiments, the final-state neutrino in each event was not observed. The numbers are too small, to date, to do more than to establish the existence of these processes. Experimenters from CERN obtained similar results by studying neutrino interaction on the free protons in propane, using film which was taken 7 or 8 years ago, before the existence of neutral currents was even suggested. It demonstrates that there should be a great deal of useful data to be obtained from the next Gargamelle run, with a propane filling and a more intense neutrino beam.

There can now be no doubt that neutrinos and antineutrinos interact with nucleons (that is, protons and neutrons) in two distinct ways. The charged-current mode is more copious, but the neutral-current mode, in which another neutrino goes off afterwards rather than a charged muon, is well established. It is even becoming possible to put realistic limits on the 'Weinberg angle', a parameter which governs the relative strength of the charged and neutral currents in the simplest unified theory of weak and electromagnetic interactions.

One interesting question still awaits a definite answer; that is, how do neutrinos and antineutrinos interact with electrons? The Gargamelle collaboration reported the observation of two events in which an electron appears to have been produced by an antineutrino interaction. Although the calculated background is small, there can be no certainty in the observation of such a small signal. But the rate is roughly what would be expected within the framework of the simplest theory, using a value for the Weinberg angle which is consistent with the neutrino-nucleon experiments. This is the first experimental evidence that the neutral neutrino current might interact with electrons as well as with protons.

Muon puzzles

There was speculation at the meeting about both new elementary particles and new interactions. One new effect is the direct production of charged leptons from hadron collisions. The leptons—electron, muon and neutrino—have never been observed to take part in strong interactions. The hadrons—the proton and neutron, the hyperons, the mesons and all of the resonant states—are the only known strongly interacting particles. They were thought to produce

leptons only in weak or electromagnetic decays, not in their strong collisions.

A group from CERN, Columbia and Rockefeller Universities in New York, and from Saclay in France, working at the CERN Intersecting Storage Rings in Geneva, has now found convincing evidence that electrons are directly produced in proton-proton collisions at the very highest observed energies. Another group from Columbia, working at the Fermi National Laboratory near Chicago, has seen the same sort of effect, with both electrons and muons coming from proton-proton collisions at somewhat lower energies. A Chicago, Harvard, Pennsylvania and Wisconsin group also has seen direct muon production at the Fermi Laboratory, and direct muon production has been reported from the even lower energy accelerators at Serpukhov in the Soviet Union and at Brookhaven, New York. All of these data have, of course, been corrected for indirect muon production by means of the weak decays of mesons. In every case the ratio of direct lepton production to pion production is about 1 to 10,000. The ratio does not vary much over the large energy span of these different machines. It also seems roughly constant as the transverse component of the lepton momentum, perpendicular to the incoming protons, is varied from 2 to 5 GeV/c.

Two sorts of explanation have been suggested for direct lepton production; the revolutionary or the merely surprising. One revolutionary explanation requires that 'charmed' particles are being produced, and decaying rapidly to normal particles including muons or electrons. 'Charm' is a postulated new quantum number, similar to the old-established 'strangeness' quantum number. It is needed to explain, among other things, the absence of strange-particle production in neutral-current weak interactions. The merely surprising explanation requires that most of the pion production in high energy proton-proton collisions actually comes from the production of massive resonances which decay to pions by the strong interaction. Some of these resonances, in particular the 'rho', the 'omega' and the 'phi' known as the 'vector mesons', also decay occasionally by means of the electromagnetic interaction to a pair of electrons or a pair of muons. Preliminary calculations, using vector meson decays, give a lepton to pion ratio of about 1 to 100,000. Nobody knows yet whether the extra factor of 10 can be found to make this calculation match the observed rate. But even if the factor can be found, and a revolutionary explanation is not needed, ideas of particular production at high energies will have been radically changed.

The Fermi Laboratory and Harvard

neutrino experiment has revealed two puzzling muon events of quite a different kind. Each seems to be the result of the interaction of a 150-GeV neutrino in their apparatus, producing two muons and a shower of hadrons. Ordinary 'charged-current' neutrino interactions contain one final-state muon, and neutral-current events have no muons. As a theorist remarked at the conference: "taking preliminary results seriously is a well known way of making a fool of yourself". Nevertheless, there is much speculation that these dimuons could be due to the decay of a totally new kind of particle. Some say 'charmed' particles again; some say it may be the 'intermediate boson' that carries the weak force, a sort of heavy photon; some say it is a heavy lepton of the kind needed in the unified weak and electromagnetic theory of Georgi and Glashow. Certainly, if this observation is correct, then no 'merely surprising' explanation will do.

Prospecting for a dead slab

from Peter J. Smith
Geomagnetism Correspondent

LITHOSPHERIC slabs descending beneath trench systems are known to have seismic velocities which are measurably higher than those in the surrounding mantle. Because such downthrusting slabs can be recognised in simpler and more convenient ways, not least by their deep seismicity, there may be little need to use the seismic velocity property to detect Benioff zones which are still active. But what about zones in which subduction has now ceased and which are seismically quiet or dead? When subduction ceases, the relevant slab, initially cooler than the mantle into which it was previously descending, will slowly warm until the thermal and compositional contrast between it and the surrounding mantle disappears; but until this process is complete the 'dead' slab may retain enough of its identity to maintain the velocity contrast. So can this contrast be used to detect the slab's presence?

That there are likely to be recently dead slabs to detect may be inferred by extrapolating known plate tectonic processes backward in time. The evolution on the western margin of North America is a good case in point and probably the most-studied example. Magnetic anomalies in the north-east Pacific suggest that a Farallon plate (sometimes called the Juan de Fuca plate or the Gorda plate) descended along the boundary between it and the North American plate until about 30 million years ago, at which time a spreading ridge between the Farallon and Pacific plates began to collide with

the western North America trench and strike-slip motion commenced along the San Andreas fault. In this way it is thought, the plate boundary along western North America began to change from a subduction zone to a transform fault. There is evidence from seismic reflection studies of the continental margin, from the occurrence of subcrustal earthquakes, from andesitic volcanism in the Cascades and from marine magnetic anomalies that north of the Mendocino fracture zone subduction may still be occurring very slowly. South of Cape Mendocino, however, subduction has ceased, although Atwater (*Bull. Geol. Soc. Am.*, **81**, 3513; 1970) has concluded that the cessation may have occurred no more than a few million years ago.

The implication here is that the remains of the Farallon slab may still lie beneath California and may still have sufficient of its original identity to produce a measurable velocity contrast. To test whether this is indeed so, Solomon and Butler (*Earth planet. Sci. Lett.*, **21**, 421; 1974) have attempted to detect such a contrast by analysing the travel-time delays of teleseismic P waves in the region. The method adopted was derived from that used by Davies and McKenzie (*Geophys. J.*, **18**, 51; 1969) to show that shallow earthquakes and explosions above a descending slab produce distinctive patterns of travel-time residuals for teleseismic P waves as a result of the velocity anomaly within the slab. The basic residuals obtained by Solomon and Butler were the travel-time delays at each station concerned for P waves from many different earthquakes and explosions. But to remove uncertainties in source locations and origin times and to reduce near-source contributions to the total travel-time residuals, the residuals actually plotted were the differences between the travel-time delays at each station and the corresponding delays at a reference station overlying what is presumed to be more uniform mantle. The sources were mid-plate earthquakes and explosions, deep earthquakes, and "carefully screened" (to avoid obvious near-source heterogeneities) earthquakes on spreading centres and transform faults.

In the absence of any detailed knowledge of the position and extent of the supposed dead slab, the stations chosen were those between latitudes 37°N and 50°N and between longitudes 116°W and 125°W at which P wave arrivals had been regularly reported during the period 1964–1970 (a selection process which eliminated all but seven stations, three of which were regarded as reference stations). The residuals obtained from various station pairs were plotted on residual-spheres, the resulting plots being a measure of the variation of travel-time delay with direction of wave

propagation in the upper mantle beneath the relevant station.

The residual-sphere for station LON in the Cascades in Washington (referred to BMO, Blue Mountain Observatory to the east) failed to indicate any systematic trends in residuals. If a high velocity slab lies in the upper mantle beneath western Washington and if its upward projection cut the Earth's surface near LON, an eastward-dipping band of negative residuals (early arrivals) might be expected. No such band was observed. But for station pairs based on the three primary stations in California (MIN in the southern Cascades, ORV and JAS along the western edges of the Sierra Nevada), a group of consistently negative residuals was observed towards the east in each case. Moreover, the average travel-time advance in the eastern quadrants of the residual-spheres (calculated in the same way for each sphere) decreased southwards from 1.2 s for MIN, through 0.8 s for ORV, to 0.5 s for JAS.

These patterns of travel-time residuals (irrespective of magnitude) are consistent with the presence of a dead slab dipping eastwards beneath California. On the other hand, they cannot be said to prove the point absolutely because the same data could in principle be explained using a model with undulations in the depth to the top or bottom of the low velocity zone. Moreover, the data are not as complete as they might be because of a paucity of seismic sources in eastern North America. But seen in the light of other evidence the case for a dead slab is more convincing. In addition to the plate tectonic inferences already quoted, support may be adduced from heat flow studies, for example. According to Roy *et al.* (in *The Nature of the Solid Earth*, McGraw-Hill, 1972), the low heat flow in the Sierra Nevada apparently requires a heat sink in the shallow (~50 km) mantle—a role that could easily be filled by the postulated slab. If this interpretation is accepted, the implication then is that between the Pacific plate and the Sierra Nevada the Farallon plate dips at an angle of perhaps no more than 10°–15°. A more detailed analysis of the travel-time data, on the other hand, suggests that east of the Sierra Nevada the dip is much more steep (possibly 40°–50°).

The southward decrease in the magnitude on the travel-time advance could result from differences in the positions of the stations with respect to the position on the Earth's surface of the upward projection of the supposed slab, or it could be due to a real southward decrease of the P wave velocity in the slab. Solomon and Butler favour the latter explanation on the grounds that the three stations are similarly

located very close to the western margin of the Sierra Nevada or the California Cascades, but admit that the evidence is not sufficient to rule out the other possibility. On the other hand, from Atwater's models, they deduce that subduction ceased beneath station MIN about 4 Myr ago, beneath ORV about 6 Myr ago and beneath JAS about 12 Myr ago. In other words, the dead slab seems to age towards the south.

This theory would offer a natural explanation for a southward decrease in P wave velocity, for the older the slab the more it will be thermally assimilated with the surrounding mantle and thus the lower will be the mantle-slab velocity contrast.

Eyeglow in butterflies

from our *Insect Physiology Correspondent*

It is a familiar observation that the dark-adapted eyes of nocturnal moths produce a conspicuous glow when viewed in a beam of light. The 'tapetum' responsible for this reflection is believed to be the rich network of air-filled tracheoles which invest the deepest levels of the retina. As Horridge (*Proc. R. Soc. Lond.*, **B179**, 98; 1973) pointed out, if the light entering one facet is confined to a single rhabdom (as in the light-adapted eye) its reflection will not emerge through another facet. On the other hand, whatever the precise mechanism of eyeshine may be, in the dark-adapted eye the scattered light may follow many possible routes within the eye and emerge through other facets.

Particular interest has been taken in the eye glow of butterflies, which can be very brilliant, and of diverse colours, in the dark-adapted state; but which disappears very rapidly on illumination. Miller and Bernard (1968) attributed this light to the flange-like taenidia of the tracheoles running vertically between the bases of the rhabdoms, which they suggested were functioning as a quarter-wave stack made up of alternating layers of air and cuticle with refractive indexes of 1.0 and 1.4 respectively. Swihart *et al.* (*J. insect Physiol.*, **20**, 359; 1974) now question this 'basal reflection theory' for the origin of eye glow in butterflies.

These authors concentrated on butterflies of the genus *Vanessa*, which show a uniform orange reflection over almost the entire eye. The band of wavelengths reflected is far narrower than was to be expected from a quarter-wave stack. The time required for the extinction of the eye glow is constant at some 5–10 s for a given eye; the cycle of extinction (and reappearance in the dark) can be repeated hundreds of times with little

variation. No detectable changes in pigment distribution can be detected. As Exner had shown, the response can be completely localised to a few ommatidia. The reflections are more intense than would be expected from a basal reflection—perhaps 20 to 50% of the incident light—and they can be upset by the slightest mechanical contact with the cornea.

Furthermore, the authors show that during light adaptation there is a photo-mechanical contraction of two specialised retinula cells; this causes the rhabdom to fold and the crystalline cone to be withdrawn away from the cornea. The elastic 'corneal process' between the cornea and the crystalline cone is stretched and its optical properties are altered. The corneal process is believed to be the source of the eyeglow reflections, the spectral properties of which will be largely determined by the overlying cornea. When the corneal process is stretched the reflections are extinguished. This 'distal reflection theory', according to the authors, has no physiological implications for vision in butterflies: these are diurnal creatures; at the levels of illumination they normally encounter the eyes are in the light-adapted state and the corneal process does not reflect—it is simply a portion of the dioptric apparatus, serving to conduct light from the cornea to the lens.

How swamp plants react to thermal pollution

from Peter D. Moore
Plant Ecology Correspondent

THERMAL pollution is a problem of the future; as nuclear reactors proliferate, so larger quantities of waste heat will be pumped into the environment causing problems of thermal tolerance to the organisms living in their vicinity. To date little is known about the effects on wetland plant communities of artificially raising the temperature, although some information exists regarding aquatic organisms.

Sharitz (*Oikos*, **25**, 7; 1974) has been able to study the effects of reactor effluent in a situation where adequate controls have been possible—in the swamp forests of the south-eastern United States. Many of the lower stretches of rivers in this area are surrounded by swamp forests which, as the term implies, are dominated by trees, such as *Acer rubrum*, *Fraxinus pennsylvanica*, *F. caroliniana* and *Planera aquatica*. In these swamps, 48% of the plant species are trees and a further 14% are shrubs and woody vines. Swamp forests experience considerable

seasonal fluctuation in water table and most of the tree species are intolerant of prolonged flooding. Even *Taxodium distichum* and *Nyssa aquatica*, which are the most tolerant to floods, are killed by lengthy exposure to a high water table.

Part of the Savannah River catchment in South Carolina is occupied by a nuclear reactor of the US Atomic Energy Commission, which pumps hot water into some of the tributary streams. One stream in the area is unaffected (providing a convenient control), two others are thermally polluted and a fourth has been recovering for more than 4 years following 14 years of thermal stress. The area therefore provides a useful setting for the study of the effect of nuclear plant discharge on swamp vegetation and the way in which the flora recovers after the activity is stopped.

The area currently polluted has water temperatures which frequently exceed 45° C and the vegetation of the area has been profoundly altered. All trees, shrubs and lianes have been destroyed and the only habitats suitable for plant growth are the islands formed from collapsed, dead timber; here some herbaceous plants, such as *Ludwigia leptocarpa* have become established. In fact the diversity (Shannon-Weaver index) of the ground flora is fractionally increased, resulting from the new microhabitats created.

The recovery area has similar stumps and logs, together with emergent, floodplain sediments which have been colonised by adventive herbs, such as *Polygonum punctatum*; a large proportion (35%) of the plants of this area are annuals. Some woody plants are recorded, including *Pinus taeda* and *Salix nigra*, but these are not species typical of the mature swamp forest, so that it is difficult to judge how long the area will take to return to the typical swamp forest if, indeed, it ever does.

The loss of woody species during flooding could be of particular concern if it resulted in local erosion and consequent silting of the Savannah River. It is unfortunate, however, that it has not been possible to distinguish between the truly thermal effects of disturbance and those resulting from a permanent raising of the water table. It is probable that the loss of trees and shrubs is due to flood intolerance rather than sensitivity to high water temperatures. Such a distinction, were it possible, would indicate whether the destruction of the swamp forest could be avoided by providing drainage conduits direct to the Savannah River. Although such action would stabilise the forest, it would not, of course, reduce the effects of thermal pollution on aquatic organisms in the river.

Photochemical war on the atmosphere

John Hampson

Centre de Recherches sur les Atomes et les Molecules, Faculté des Sciences, Université Laval, Quebec, Canada

Professor Hampson believes that many scientists have not recognised the potential danger of thermonuclear warfare. He outlines some of the changes in the photochemical regime of the atmosphere, which may be wrought by nuclear explosions, and suggests that these effects must be considered in future talks on arms limitation.

A FIVE per cent increase in the atmospheric content of ozone in recent years has been attributed to the recovery of the atmosphere following the injection of NO_x by nuclear tests during the winter of 1961–62¹. Estimates of the theoretical quantity of NO_x generated have been presented by several investigators^{2,3}. If the NO_x is not swept out of the stratosphere by the change of heating and transport induced by the new ozone structure, then, should the amount of nuclear discharge into the atmosphere increase by one order of magnitude, the total ozone content may be halved. At first sight it seems that the variation should follow a square root law. If the decreased screening by ozone, and the consequent increase in NO production is allowed for, however, then for particular values of the reaction rate coefficients and circulation parameters a linear dependence is a closer estimate of the maximum possible effect (within the possible range of errors). A further increase of one order of magnitude could reduce the total ozone in the atmosphere to a fraction of its present value. It is appropriate to enquire into the effect of such radical changes in the ozone content and the circumstances in which they might occur.

The photochemical behaviour of the stratosphere is far from fully understood, and the chemical effects of high yield, high altitude nuclear explosions have never been measured and reported. It is probable that there are changes besides those which are predicted by the simple NO_x theory. That is, however, no reason to reject the theory, for it forms a solid base for future work. It is difficult to believe that mankind can put into the chemosphere an energy comparable to the chemical energy of the ozone layer (~3,000 Mton) in less time than it took to create the layer, and still expect the chemosphere to remain intact.

It has been assumed⁴, and no alternative view has been presented, that the evolution of life on the exposed surface of the planet began with the formation of the ozone screen. The removal of this screen would mean that conditions of ultraviolet illumination at the surface would become similar to those of Precambrian days, and would presumably eliminate all surface life. The biosphere involves such a complex pattern of interacting influences that it is impossible to assess the effects of drastic reduction in ozone. 'Reasonable' approximations must be used. The ozone content in the path from the Sun to the summer pole is double that in the shortest Sun-surface path at the equator. Halving the ozone abundance would create a situation where the ultraviolet input is everywhere greater than it was previously. For want of a better yardstick I shall assume that this is the degree of ozone reduction which

could destroy the present biosphere. The argument here is simply that the biosphere has adapted to the available ultraviolet illumination, and a critical condition exists. Following a halving of the ozone content no living organism would be able to find a place on the surface of the Earth where the ultraviolet input was equal to or less than that previously available anywhere.

It is instructive to consider the circumstances in which a thermonuclear war could occur, halving the effectiveness of the ozone screen. The structure, deployment and potential use of nuclear weapons are dictated by an analysis of the probable damage and potential injury which would be inflicted on the 'opponent'. It seems reasonable to assume that it will occur whenever the predicted outcome would be more favourable to the instigator than any alternative action at his disposal. There is no evidence that any of the nuclear powers, or any of the nations who are allegedly attempting to forestall nuclear proliferation through the United Nations, have made any attempt to consider the photochemical problem in their deliberations. It must therefore be assumed that the decisions on thermonuclear war are based on a hypothetical body count of potential victims. That is the way the issue is posed in the published studies of nuclear war, particularly exemplified in the account by Kahn⁵.

To knock out one of the major powers, the United States, the USSR or China, 5,000 Mton must be accurately delivered, somewhat less would be required to destroy Europe. If the concepts and calculations of Johnston¹ are correct the use of the minimal deterrent would halve the ozone content. In these circumstances, the deterrent as such is a myth and becomes one of Kahn's Doomsday Machines⁶.

If NO_x is the critical reactant which is destroying the ozone then the effects of thermonuclear weapons may be greater than the estimates I have given. These estimates are based on low level bursts in which the NO_x concentration is calculated from consideration of the thermodynamic equilibrium in the fireball at a temperature of 2,000 K. A high proportion of the nitrogen atoms produced before and during that stage, during the development of the fireball, are recombined as N_2 , and the NO_x production represents a small proportion of the total energy of the nuclear burst. This is not the case for an explosion at high altitude, when the energy density of radiation below the burst point, at the altitude of maximum NO production, is sufficiently small that recombination through $\text{NO} + \text{N} \rightarrow \text{N}_2 + \text{O}$ plays a proportionally smaller role. If the concentration of N is small compared with that of O_2 , then the bulk of the NO produced by $\text{N} + \text{O}_2 \rightarrow \text{NO} + \text{O}$ may not be removed subsequently in the competing reaction between N and NO. High altitude explosions are much more efficient at producing NO than are ground level explosions. It is fortunate that the tests in 1962–63 were conducted in the lower atmosphere and not at high altitudes. Otherwise there may have been such a large production of NO that any subsequent debate on atmospheric chemistry would have been both impossible and superfluous.

Each of the two major nuclear powers seems to have

a stockpile in excess of the critical value, 5,000 Mton, and to be continually jockeying for a uniquely unassailable position. The only way this can be achieved is by using ballistic missile defence, and the nations concerned can be expected to make this a priority item of defence research. That constitutes a somewhat greater danger to the ozone screen than do the offensive weapons. It not only increases the required number of offensive weapons but also creates more NO per unit of energy released into the atmosphere, because interceptions must be made at high altitudes. Some years ago there was a far fetched, fanciful concept that the release of 1,000 Mton or so in the equatorial E region might have produced an artificial Van Allen belt of sufficient intensity and duration to clean up a great deal of the debris and decoys which clutter and confuse the radar return from a missile warhead. It would not have worked, but it is disturbing to discover that such concepts are advanced with absolutely no consideration of the potential effects on the Earth's photochemical system. Even the 'orthodox' defence systems agreed to in the Strategic Arms Limitation Talks (SALT) are themselves a major threat to the photochemical environment. Several hundred interceptors are involved, each with warheads in the Mton range. The actual yields of the interceptor warheads have not been published. Assuming that they may now, or eventually, be set at 10 Mton, which would give the maximum capacity for damaging the re-entry warhead and cleaning up the accompanying assorted objects, then the defence systems defined by SALT, which themselves give only a token and limited defence, would be capable of injecting 2,000 Mton into the atmosphere. They would do this at high altitudes and therefore have a much greater potential for modifying the NO_x environment than the low altitude bursts.

The threat to the ozone layer posed by thermonuclear discharges is much more serious than that posed by contamination from supersonic transport (SST) flights. We have time to analyse the photochemical environment and assess the potential effects long before widespread SST flights add an appreciable amount of NO_x to the environment. The bigger issue is whether the nuclear deterrent is a Doomsday Machine. It is astonishing that none of the deliberations on reduction of nuclear arms pay the slightest attention to this photochemical parameter. Surely there is a need to establish whether there is an absolute limit to nuclear war, involving energies considerably smaller than those at present used as a deterrent. Such information could be used as a lever to cajole the nuclear powers to move towards a more positive view of the need for arms control. Johnston¹ has performed a considerable service in drawing attention to the potential fragility of the ozone screen. It is to be hoped that increased attention will be paid to the effects of thermonuclear weapons and that this may provide a rationale for the reduction and control of nuclear armaments.

A *prima facie* case for NO as the agent controlling ozone having been clearly established, it should be noted that there are many factors of the chemistry and circulation of the ozone layer, and of the interrelation between the layer and the rest of the Earth-Sun system which have to be researched before the case is proven. This should be no excuse for disregarding the potential danger. It does, however, imply that we may find that nuclear weapons could exert dangerous effects in other, more subtle, ways.

A single, 10 Mton weapon exploded in space, less than an Earth's radius away, throws out about as much energy at the Earth as does the solar wind during the passage of the interplanetary magnetic field sector boundary. Can it be assumed that this could cause effects commensurate with those deduced by Roberts *et al.*?² If a 10% change in vorticity could occur with a single weapon, what would a space war do? We need to examine whether this effect

stems from a chemical source (see ref. 6).

There seems to be a disparity between the hydrogen escape deduced from observations at the exobase, and models of H transfer from the lower atmosphere to the exobase. In view of this can we neglect the possibility that a nuclear war in space would lower the hydrogen concentration above 40 km, and through an increase in the upper atmospheric ozone content reduce the formation of NO and increase the total ozone content?

We simply do not know the answers to many important questions. Granted an adequate programme of measurements, far more ambitious than that envisaged today, and sufficient clairvoyance (omniscience might be a better term) the minimum time necessary to assess natural variations resulting from solar activity in the chemosphere will be one solar magnetic cycle of 20 years. There can be little prospect of accurately defining how contamination can compare with or can couple into the natural variations in a shorter period.

We might as well accept both of the apparently contradictory propositions that contamination by NO_x can change the ozone abundance and that the observed increase in ozone is real but is not related to changes in the NO_x content.

From Johnston's estimates¹ it seems reasonable to infer that a fleet of 100 Concorde might change the ozone content over a period of 5 years to an extent comparable with the observed rate of increase of ozone during the decade 1960-70. This fleet seems to correspond to the maximum scale of production and deployment to be expected between now and 1980. There seems to be adequate time between now and 1980 to refine the observations and theoretical analyses of the chemosphere to the point at which we can estimate a 'limiting, scale of operations for supersonic aircraft and other potential sources of stratospheric contaminants. This period of grace should be used to ascertain whether the observed increase in ozone during 1960-70 continues into the next decade and is therefore not related to recovery from the nuclear tests.

Contamination by CO₂ is recognised, but can hardly be averted at the moment. Studies of the effect of changes in the CO₂ content have been limited to evaluations of the greenhouse effect in the lower troposphere. No attention has been paid to possible alterations of temperature and vertical stability above the tropopause. These can modify the transport of reactive minor constituents, and readjust the photochemical balance. There is insufficient information on the details of the nitrogen cycle. We cannot be absolutely sure that the scale of human modification of the critical elements in the cycle will have no effect.

The effects of nuclear weapons are another matter. The majority of the scientific community fail to recognise the potential danger from a change in the chemical envelope of the Earth. They thus fail to consider the possibility of defining a limit to nuclear activity, which can be universally agreed upon and could set the stage for arms control. So long as the nuclear problem is viewed as one of international rivalry there can be little prospect of any control because it will always seem that one nation can gain an advantage over another. Kahn's dictum that a Doomsday Machine can never be used is a reasonable enough basis for arms control. But this depends on our being able to recognise such a machine.

The main motivation for stratospheric research should be the desire to delimit the effects of general contamination and to define the absolute limit of nuclear activity which would constitute 'The Doomsday Machine'.

The fine structure (both spatial and temporal) of the reactive minor constituents deserves careful study. Johnston *et al.*¹ and Goldsmith *et al.*³ present arguments that it is the long term global effects of nuclear tests on the ozone content, and not short term local effects, which

should be considered. This is an oversimplification. The form of polar stratospheric circulation and the characteristics of the auroral belt were abnormal during the winter of these tests. It is always possible that there have been more complex interrelationships between the tests and the photochemical regime than has been supposed.

All the parameters involved must be studied, and all potential, alternative models of stratospheric chemical behaviour must be included in order to avoid a superficial interpretation which fits the selected facts visible from the fraction of the iceberg that can be seen at present.

Hopping losses in polarisable dielectric media

A. K. Jonscher

Department of Physics, Chelsea College, University of London, Pulton Place, London SW6 5PR, UK

The loss in most dielectric materials shows a component that is 'flat' in frequency over several decades and does not depend strongly on temperature. The usual interpretation as the sum of many Debye-like loss peaks is criticised and a new model is proposed in which charge carriers hop between localised sites in a polarisable medium.

THE dielectric loss $\chi''(\omega)$ is defined as the imaginary component of the complex dielectric susceptibility

$$\chi(\omega) = [\epsilon(\omega)/\epsilon_0] - 1 = \chi'(\omega) - i\chi''(\omega) \quad (1)$$

where $\epsilon(\omega)$ is the dielectric permittivity, ϵ_0 is the permittivity of free space and ω is the radian frequency. The corresponding a.c. conductivity is $\sigma'(\omega) = \epsilon_0\omega\chi''(\omega)$ and this may exceed the d.c. conductivity σ_0 by some orders of magnitude. The experimentally observed frequency dependence of dielectric loss in a wide range of materials may be expressed by the empirical relation

$$\chi''(\omega) = \Lambda(T)\omega^{n-1}$$

where $\Lambda(T)$ is weakly dependent on temperature but is not generally characterised by a simple activation energy and the exponent n lies in the range $0 < n < 1$, with typical values between 0.6 and 0.95. This implies that the loss is 'flat' in frequency, often over many decades in the normally accessible range between sub-audio and microwave frequencies¹⁻⁵. In general, there seems to be no correlation between the values of σ_0 and $\sigma'(\omega)$ for various materials.

There are two different approaches to the theoretical interpretation of the flat loss given by equation (2). The first is applicable to materials which are believed to contain molecular dipoles and it involves the assumption of a suitably wide distribution function $g(\tau)$ of dipolar relaxation times τ , covering several powers of ten⁶.

The second approach is that of the electronic hopping school which considers the frequency dependence of the localised charge carriers hopping in a random array of centres^{3-5,7,8}. This 'sequential hopping' model is in many ways equivalent to the former approach, replacing the distribution of dipolar relaxation times with a corresponding distribution of hopping times. But it also provides for the d.c. conductivity in the limit of zero frequency. Given a sufficiently wide distribution of intercentre spacings and of their relative energy differences, it is possible to obtain a frequency dependence of the type given by equation (2) and extending over a reasonably wide range of frequency. Another explanation invoking local atomic movements in disordered solids has been proposed by Pollak and Pike⁹.

Hopping model

I have expressed some doubt about the universal applicability of the sequential hopping model in view of the fact that a very wide range of different materials show a very similar dependence on frequency and the absolute values of the dielectric loss fall in a relatively narrow range². The lack of correlation between σ_0 and $\sigma'(\omega)$ is also unexpected in the hopping model, as is the apparent independence of $\sigma'(\omega)$, but not of σ_0 , on pressure^{10,11}. Furthermore, the same frequency dependence is seen in relatively thick samples in which sequential hopping represents a plausible model and in very thin (1 to 3 nm) samples, in which there is no scope for more than one hop¹².

So I believe that there is sufficient uncertainty about the origin of the flat dielectric loss due to hopping carriers to make it desirable to propose an entirely new physical model in order to evaluate its merits and consequences. I consider that an essential feature of this model must be its general applicability to a wide range of semiconducting and dielectric systems. It is relevant to recall here that it has been suggested that the flat loss in some conventional dielectric materials may also be due to electronic hopping, in view of the known presence in these materials of low mobility carriers^{13,14}. A detailed analysis of the behaviour of dipolar systems will be published elsewhere.

Hopping in a polarisable medium

In the conventional picture one considers hopping as occurring between two localised levels, each of which is uniquely defined in space and in energy (Fig. 1a). This model is applicable to media in which the polarisation responds sufficiently rapidly to the appearance of an electron on any one site so that the transition may be said to occur effectively into the final state. But if the polarisation of the dielectric medium responds relatively slowly in comparison with the time taken by the tunnelling process, as is the case almost by definition in all materials showing a strong dispersion of conductivity with frequency, then the energy level picture must be as shown in Fig. 1b. The 'empty' and the 'occupied' states are separated by a polarisation energy W_p , due to the relaxation of the surrounding lattice and carriers.

In this case, the transition from a localised level i into an equivalent unoccupied level j having the same energies may be considered to occur in three stages (Fig. 1c). Process 1 is the thermal excitation of the carrier into a virtual state corresponding to the unrelaxed energy of an empty state. The following tunnelling transition (2) is not activated and the process is completed by a gradual relaxation, 3, into the ground state of the newly occupied centre.

Fig. 1 Localised energy levels in hopping between pairs of centres. *a*, Hopping in a medium in which polarisation relaxes very rapidly—the conventional hopping system; *b*, full and empty centres in a medium in which polarisation relaxes slowly; *c*, three stages of hopping between two centres as in *b*.

In thermal equilibrium detailed balancing determines the transition rates $\gamma_{ij}^0 = \gamma_{ji}^0 = 1/\tau_0$ at which the gain of energy from process 3 exactly balances the energy required by process 1. For this mechanism to be applicable we require that the equilibrium transition time τ_0 should satisfy the condition

$$\tau_0 \gg \tau_p \quad (3)$$

where τ_p is the relaxation time for the polarisation process, since otherwise the carrier would be re-excited before it has had a chance to relax. This condition may be expected to be satisfied at low temperatures, such that $kT < W_p$, and at higher temperatures the system becomes effectively the same as the model of Fig. 1*a* corresponding to a rapidly polarisable medium, since in this case the model has no time to respond to the rapid transition rate and adjusts itself only to the mean occupancy.

The proposed slow polarisation mechanism is not necessarily confined to materials with polar lattices—it may also be expected in otherwise non-polar materials which contain hopping carriers responding to any changes of the spatial distribution of other carriers in their neighbourhood.

I now consider an assembly of N identical pairs of localised sites, each pair containing one electron capable of jumping between the two sites constituting the pair. I shall assume for simplicity that the sites have the same energies—this does not entail any loss of generality of the subsequent argument, while simplifying the discussion. In the absence of external fields the occupancies of the individual sites are equal on average and are $f_0 = 1/2$.

If an external field is applied to the system favouring 'downstream' transitions and discouraging 'upstream' ones, the occupancies of the corresponding centres change by $\pm f'$ resulting in a net polarisation

$$P = ea \sum_s f'_s \quad (4)$$

where a is the distance between sites and the index s denotes summation over pairs of centres.

The perturbation of the occupancies of the system by the applied field must result in a net loss of energy W_p for each transition in excess of the equilibrium rate $1/\tau_0$. We argue that at this excess transition rate the energy derived from the relaxation process 3 in Fig. 1*c* can no longer be recovered and is lost to the phonon system as heat. The rate of energy loss may thus be expressed in the form

$$dW/dt \propto W_p |\gamma_{12} - \gamma_{21}| = W_p |df'/dt| \propto |dP/dt| \quad (5)$$

since the excess occupancies f' are directly related to the excess

transition rates. The absolute value signs imply that the energy loss occurs for either sign of the rate of change of f' . Assuming now an alternating electric field at a frequency ω , $E = E_0 \sin \omega t$, we may define a frequency-dependent complex susceptibility $\chi(\omega) = P/E$, implying a phase lag between P and E due to the presence of loss.

The physical nature of this loss may be envisaged by considering the extra energy required from the alternating field to cause the increased transition rate from the relaxed states on reversal of the sense of polarisation. This energy is derived from the phase lag between P and E .

Frequency dependence of the susceptibility

To obtain the energy loss per cycle, W_c , we must integrate the rate given by equation (5) over the half period during which $dP/dt > 0$. During the other half cycle the loss arises on the opposite sites in the pairs whose occupancy is being increased at the time. The loss per cycle is therefore proportional to the amplitude of the polarisation P , but the frequency ω does not appear in the result of the integration. So

$$\chi'' \propto |\chi(\omega)| = [\chi'^2 + \chi''^2]^{1/2} \quad (6)$$

regardless of the frequency ω . However, this relation can only be satisfied generally if

$$\chi''(\omega) \propto \chi'(\omega) \quad (7)$$

that is, if the real and imaginary components of the complex susceptibility are the same functions of frequency, implying that

$$\chi''(\omega)/\chi'(\omega) = \text{constant with respect to frequency} \quad (8)$$

I note, however, that $\chi'(\omega)$ and $\chi''(\omega)$ must obey the universally applicable Kramers-Kronig relations which in the extended frequency range $(-\infty, \infty)$ may be written in the form of a Hilbert transform

$$\chi'(\omega) = (1/\pi) \int_{-\infty}^{\infty} \frac{\chi''(x) dx}{(x - \omega)} \quad (9)$$

and a similar expression for the real and imaginary parts reversed and with a negative sign in front of the integral. The integral is to be taken here in the sense of the Cauchy principal value.

It is a property of Hilbert transforms that equation (9) and its counterpart can only be satisfied with the condition (7) by the following functions¹⁸:

$$\chi''(\omega) = A \operatorname{sgn} \omega |\omega|^{n-1} \quad (10)$$

and

$$\chi'(\omega) = A \tan(n\pi/2) |\omega|^{n-1} \quad (11)$$

where A is a constant and the exponent of the power law satisfies the condition $0 < n < 1$. This implies that the ratio (8) satisfies the condition:

$$\chi''(\omega)/\chi'(\omega) = \cot(n\pi/2) = \tan[(n-1)\pi/2] \quad (12)$$

so that the ratio of the real and imaginary parts of the susceptibility is directly related to the exponent n .

The upper frequency limit for the applicability of the relations (10) and (11) may be expected to be $1/\tau_0$, the equilibrium transition frequency, since beyond this limit the polarisation would cease to respond to the applied field, just as in the case of the Debye dipolar or hopping processes beyond the reciprocal relaxation time. At the lower end of the frequency spectrum, the ultimate requirement is that the loss must go to zero as ω tends to zero, so that $\chi''(\omega) \propto \omega$ at very low frequencies. In many non-polymeric systems this region is not accessible experimentally because of the onset of d.c. conduction which dominates the dielectric loss. The expected frequency dependence of loss for a single set of hopping pairs is therefore as shown in Fig. 2.

Temperature dependence of loss

Up to this point the analysis was deliberately confined to the discussion of the frequency dependence of dielectric loss, since this could be obtained with the minimum of specific assumptions relating to the relaxation mechanisms. An extension of the

Fig. 2 The frequency dependence of the real and imaginary parts of the complex dielectric susceptibility, $\chi(\omega) = \chi'(\omega) - i\chi''(\omega)$ showing the 'flat' loss accompanied by a similar frequency dependence of χ' and the cutoff at high frequencies above the reciprocal equilibrium transition time, $1/\tau_0$. a, $\chi' \propto \omega^{n-1}$; b, $\chi'' \propto \omega^{n-1}$.

analysis to cover the dependence of loss on temperature would require more detailed assumptions about the nature of the hopping transitions than we are able to make at present.

It may be stated, however, that the temperature would be expected to affect several parameters relevant to the present analysis. The equilibrium transition rate $1/\tau_0$ is certainly thermally activated and the polarisation relaxation time τ_p might be likewise, although the extent of their dependence on temperature may be quite different. Since the relative magnitudes of τ_0 and τ_p determine the applicability of the present analysis, equation (3), as distinct from the conventional Debye-like hopping, some of the contributing mechanisms may be either brought in or eliminated according to the prevailing circumstances.

Distribution of hopping parameters

The idealised model used so far in the present analysis is unrealistic in several important respects. Any real hopping system must contain a distribution of hopping parameters and it may also involve spatial distributions of centres which make possible multiple sequential hopping. In addition, the spatial distribution of the axes of the hopping pairs is normally isotropic so that the effective field is not E but $E \cos \theta$, where θ is the polar angle of the pair with respect to the field E .

The point to be noted in the present analysis is that in the presence of several sets of hopping parameters, or even of a continuous distribution, we are summing flat-loss characteristics instead of summing loss peaks. The final shape of the $\chi''(\omega)$ curve is therefore much less sensitive to the nature of the distribution of hopping parameters than would be a sum of Debye-like loss mechanisms. Of special significance is the point that the range of hopping relaxation times τ_0 does not have to correspond to the experimentally observed range of validity of flat-loss power-law dependence on frequency.

It can easily be envisaged that one of the principal effects of the presence of a distribution of hopping parameters may be an increased temperature dependence, as some of the more strongly activated mechanisms become progressively 'frozen out' with falling temperature.

Discussion

Here I have proposed a hopping model in which the carriers suffer an almost frequency-independent loss of energy arising from a relatively slow relaxation of polarisation in the dielectric matrix in which they hop. This should be contrasted with the frequency-dependent loss normally associated with hopping conduction in nonpolarisable media and also with dipolar

rotations, both of which give rise to characteristic loss peaks as functions of frequency.

One direct consequence of the present model is the fact that both the real and the imaginary parts of the complex dielectric susceptibility $\chi(\omega)$ have the same frequency dependence. The power-law dependence given by equations (10) and (11) then follows as a natural consequence of the Kramers-Kronig relations, leading to a flat frequency response even in the presence of only one single set of hopping parameters. This means that in the present model it is not necessary to invoke any special distribution of hopping or dipolar relaxation times to explain the very widely experimentally observed flat frequency dependence of dielectric loss, as would be the case with the summation of individual Debye-like loss peaks. In particular, it is not necessary to postulate sequential hopping over many sites distributed randomly in space and in energy, as is clearly the case with d.c. conductivity. This makes it much easier to understand the similarity of the experimentally observed behaviour of relatively thick and of very thin samples. It is also clear that the dielectric loss has nothing to do with the d.c. conductivity σ_0 of the material, since they are due to essentially different processes. The lack of dependence of loss on hydrostatic pressure is also understood in terms of the insensitivity of the polarisation energy W_p to pressure, as opposed to the strong dependence of the hopping probabilities themselves, especially the most difficult ones determining the d.c. conductivity.

The present analysis is deliberately confined to a very general model, making the minimum of assumptions about the specific properties of any particular model under consideration. I feel that when we are confronted with the case of a very widely observed behaviour, the first task is to show that this behaviour is consistent with a model postulating only a very generally applicable property—in the present instance the existence of a slow relaxation of polarisation in the dielectric matrix in which charge carriers move by hopping.

A comment is indicated about the relation between the approach proposed in the present paper and the earlier theories of sequential hopping^{3-5,9}. These theories may well be applicable to certain materials which have the required density and distribution of localised levels, for example chalcogenide glasses in which there is also a reasonable correlation between the d.c. and a.c. conductivities. I suggest, however, that the present model offers a wider framework in which it is possible to understand the observed behaviour of many materials to which the other theories could not be applied so easily.

Chemical and biological evolution of a nucleotide-binding protein

Michael G. Rossmann, Dino Moras & Kenneth W. Olsen

Department of Biological Sciences, Purdue University, West Lafayette, Indiana 47907

Three-dimensional alignment of the common nucleotide binding structure in dehydrogenases, kinases and flavodoxins permits the recognition of homologous amino acids when sequence comparisons alone would fail. Minimum base changes per codon can then be used to measure evolutionary distances which suggest that this structure was present during precellular evolution.

A COMMON structural domain¹ whose function is to bind nicotinamide adenine dinucleotide (NAD) has been found in lactate dehydrogenase (LDH)^{2,3}, in soluble malate dehydrogenase (sMDH)⁴, in liver alcohol dehydrogenase (LADH)⁵ and in glyceraldehyde-3-phosphate dehydrogenase (GAPDH)⁶. Rao and Rossmann⁷ showed that the same structure was utilised to bind flavin mononucleotide (FMN) in flavodoxin⁸⁻¹⁰. They also showed that this structure consists of two smaller units the function of each being to bind a mononucleotide. Buehner *et al.*⁶ proposed an evolutionary tree which traces the incorporation and evolution of the mononucleotide-binding structure in various dehydrogenases and in flavodoxin. Further data on the three-dimensional structures and amino acid sequences of some dehydrogenases and flavodoxins are now available which permits the evaluation of the proposed evolutionary tree more precisely. We show here that the position and sequence of the nodes in this tree are consistent with the molecular data, and that a rough time scale for these events can be proposed.

Independent support for the evolutionary tree comes from a study of redox potentials and the evolution of biological electron transport^{11,12}, suggesting a common origin for NAD and flavin-binding proteins. Furthermore, structures similar to the mononucleotide or dinucleotide-binding protein fragment have been found in phosphoglycerate kinase¹³ (Bryant *et al.*¹⁴ suggest an alternative solution) and tentatively in adenyl kinase¹⁵. Both these enzymes need to bind AMP, ADP or ATP. Similarly a flavodoxin-like structure has been recognised tentatively in rhodanese¹⁶ whose biological function is not fully established but is known to bind flavin FAD FMN and NAD.

Structural alignments

The nucleotide-binding protein discussed above consists of a parallel sheet formed by three extended polypeptide strands. The first two are connected by an α -helix, and the last two by

Fig. 1 Diagrammatic representation of a dinucleotide-binding protein. The amino termini of the strands in the β -pleated sheet are closest to the viewer. The dinucleotide binds to the carboxy termini of the strands in the sheet.

either an α -helix or another, less well defined, structure. In dehydrogenases the secondary structural features of the dinucleotide-binding fragment have been termed β A, β B, β C, β D, β E and β F within the β -pleated sheet, while the helices are labelled α B, α C, . . . (Fig. 1). This nomenclature was originally devised for the LDH structure³. Helices α B and α C connect strands β A with β B and β B with β C, respectively. They are on the same side of the sheet. Along the polypeptide chain, the sequence β A, α B, β B, α C, β C forms the first (adenine) nucleotide-binding fragment, while the second (nicotinamide) nucleotide-binding fragment is related by an approximate two-fold axis. The fold of each fragment has the same unique band.

Fig. 2 Hydrogen bonding diagram of β -pleated sheet region in (top) dogfish apo-LDH and (bottom) lobster holo-GAPDH. Amino acids with thick outlines have residues facing into hydrophobic pockets between the β -pleated sheet and α helices. The hydrophobic character of these residues is strongly conserved (Table 1).

There is a greater conservation of the structure of the sheet region than of the helices. For example, in LADH and GAPDH the helix α D is missing, while in LDH and s-MDH it forms part of a flexible loop which undergoes a large conformational change during catalysis. The greater conservation of the parallel pleated sheet region can be seen readily in Fig. 2 where the hydrogen bonding within the sheet has been depicted for dogfish apo-LDH and lobster holo-GAPDH. When these bonds are equivalently aligned, with due regard for the direction of polarity of the peptide chain, then the orientation of the C_{β} atom in each amino acid side chain must also be aligned. Hence superposition of the hydrogen bonding provides a sensitive method of determining homologous amino acids in equivalent β -sheet regions of different nucleotide-binding fragments. The atomic coordinates of the equivalenced C_{α} atoms were taken to set up an approximate rotation matrix to superimpose the two molecules being compared. This was then refined to minimise the sum of the square of the distances between equivalenced atoms⁷. With this alignment other residues, not in the sheet, but nevertheless following the same

folding sequence could be equivalenced and incorporated into the refinement procedure.

The amino acid alignments shown in Table 1 are thus based on three-dimensional structure, while the character of the amino acids has been determined chemically. Since Rao and Rossman⁷ have pointed out similarity of structure between a part of subtilisin^{17,18} and a mononucleotide-binding fragment, with the aromatic specificity pocket of subtilisin corresponding to the adenine-binding pocket of the dehydrogenases, this comparison has been included in Table 1. Results for individual comparisons among the dehydrogenases are shown as a matrix in Table 2. The resultant alignment of the bound nucleotides is best seen in a series of stereographic diagrams. The C α

backbone of the NAD-binding fragment of LDH has been used as a standard of comparison. In Fig. 3, LDH is compared with the dehydrogenases GAPDH and LADH, in Fig. 4 comparisons are made with phosphoglycerate kinase¹³ and flavodoxin and Fig. 5 shows a comparison of the AMP-binding fragment with the MNN-binding fragment in LDH.

Sequence homologies with GluDH

The alignment of the glutamate dehydrogenase (GluDH) sequences¹⁹ is not based on structure but on amino acid sequence homologies alone. Different methods of testing sequences for homologies in distantly related proteins have been reviewed by Haber and Koshland²⁰, Barker and Dayhoff²¹ and others. The procedure described by Jukes and Cantor²², which depends on counting minimum base changes per codon, has been used here. By far the best alignment was found in comparing residues 1 to 38 in GAPDH with 245 to 283 in bovine GluDH corresponding to β A, α B and β B (Table 1). This corresponds to the most conserved part of the NAD-binding structure and furthermore the character of important amino acids was maintained.

The glycine in position 28 of LDH is strictly conserved as any larger residue would cause steric hindrance to the binding of the ribose ring. The cause of conservation of the glycine in position 33 of LDH is probably related to its position on helix α B immediately opposite the β -pleated sheet. The conservation of LDH aspartate 53 (changed to glutamate in GluDH) at the end of β B must be related to its function of binding the O2' atom in the adenine ribose³. The alternate hydrophobic residues in the β -pleated sheet is also quite outstanding.

Although GluDH is known to have two independent binding sites for NADH or NADPH²³ the sequence comparison

Fig. 3 Superimposed dinucleotide-binding domains using LDH as a standard. The LDH C α backbone is shown in dark as is its NAD coenzyme. Residue numbers are given for LDH only. Fig. 4 Comparison of (a) phosphoglycerate kinase (PGK) and (b) flavodoxin with LDH. Conventions used are described in Fig. 3. The black ball is the Mg^{2+} site in PGK.

could only identify one truly significant portion of the polypeptide chain which compares with the known NAD binding domains in other dehydrogenases.

The alignment shown in Table 1 for GluDH with GAPDH is different from that given by Smith *et al.*²⁴ or the two comparisons given by Engel²⁵, one of which contains Smith's shorter sequence. The alignment given here shows 1.00 minimum base changes per codon with respect to lobster GAPDH as opposed to 1.48 and 1.53 for Engel's relationships. Furthermore, Engel aligns two GluDH sequences with residues 198–261 of GAPDH. However, this region of GAPDH belongs to the domain which supplies catalytic residues and generates substrate specificity, a domain which might be anticipated to be special to GAPDH. Williams and Wilkins²⁶ point out that Engel's alignments were based on doubtful statistical procedures.

Measuring evolutionary divergence

A relative estimate of the time since the divergence from a common ancestor (or node in an evolutionary tree) can be obtained by comparing amino acids of related proteins. Margoliash and Fitch^{27,28} used the amino acid sequence to show homologous alignments between proteins and then the mean change between the sequence can be measured by various scoring procedures to determine evolutionary distance. In this article (except for the GluDH comparisons) three-dimensional structure has been used to obtain alignments, because of its

greater conservation over amino acid sequence. Every pair of structurally equivalent amino acids can then be examined for their genetic relationship.

It is reasonable to assume that the probability of any one amino acid changing to any other is inversely proportional to the minimum number of base changes. Thus there can be 0, 1, 2 or 3 base changes or on the average 1.5 base changes per codon. If the actual genetic code is taken into account, then the average number of minimum base changes required is 1.57 to change any one amino acid to any other. If, further, the natural frequency of amino acids²⁹ is considered, this number changes to 1.51. Whether or not an observed minimum base change per codon is significantly lower than a random variation will depend on its distance from the assumed random level. When additional independent data (such as three-dimensional structures) are available, comparisons are of greater significance than when only sequence information is at hand. Thus a combination of structure and sequence permits the measurement of more distant evolutionary relationships.

The minimum base change per codon can be taken as a measure of relative evolutionary distance, that is the elapsed time since the occurrence of a common ancestor for divergent events. This measure is unlikely to be exactly linear with time if no correction is made for back mutations. Another cause for possible deviation from linearity is that the rate of accepting point mutations may have been different at different times. In general, however, a uniform acceptance rate is a reasonable assumption for a given protein. For GAPDH the observed minimum base change per codon between the pig and yeast

Fig. 5 Superimposed AMP and NMN mononucleotide-binding fragments in LDH. The AMP binding domain is shown with dark bonds and is numbered. The corresponding numbering for the NMN binding fragment can be derived from Table 1.

enzyme in the nucleotide binding protein (residues 1–149) is 0.59, but only 0.35 for residues 150–331. Presumably the differing functions of the two domains within a single polypeptide chain¹ impose different rates of evolution. Thus our estimates of divergence among dehydrogenases have been taken only within the nucleotide-binding domains.

A time scale for evolution

The evolutionary tree suggested by Buehner *et al.*⁶ has been

expanded as shown in Fig. 6. Observed minimum base changes per codon are also related to a probable time at each node. The divergence of the mammalian line from Aves can be placed about 3×10^8 yr ago (node 1, Fig. 6), from Arthropoda about 6×10^8 yr ago (node 2, Fig. 6) and from Fungi about 1.2×10^9 yr ago (node 3, Fig. 6)^{30,31}. The presence of the NAD-binding protein in cytoplasmic and mitochondrial dehydrogenases implies that it originated more than 1.5×10^9 yr ago when mitochondria were possibly incorporated into proto-eukaryotes³². Probably, however, this structure is a good deal older as it would have been required in the earliest prokaryotes for glycolysis around 3.2×10^9 yr ago³³. If it is assumed that simple polypeptides and nucleic acids had gained the ability to perform energy transfer steps and primitive copying processes during precellular evolution³⁴ we might expect to find the mononucleotide-binding protein before 3.2×10^9 yr ago. It is also reasonable to assume that it was formed sometime after the age of the Earth 4.5×10^9 yr ago³⁵.

Figure 6 shows that, the larger the age associated with the node, the greater is the minimum base change per codon consistent with a divergent evolutionary process from a single common ancestor. That alternative nucleotide-binding proteins exist is, however, evident in the structures of RNase³⁶ and staphylococcal nuclease³⁷. Nevertheless, it might be anticipated that the basic structure shown in Fig. 1 will frequently be found where there is requirement (especially an old and basic requirement) for binding nucleotides. Examples might be amino acid tRNA synthetases, ribosomal proteins and virus coat proteins. The recognition of this structure by sequence homology or from X-ray structure determinations may also give guidance as to function where none is definitely known.

We thank Dr Martha Ludwig, Biophysics Research Division, University of Michigan, Ann Arbor, for information on the hydrogen bonding scheme in *Clostridium* MP flavodoxin and the related amino acid sequence allocations before publication¹⁰. Similarly we thank Dr Susan Taylor for information on some unpublished segments of the dogfish LDH amino acid sequence and to Drs Colin Blake and Carl Brändén for atomic coordinates of PGK and LADH, respectively. We thank Drs A. Liljas,

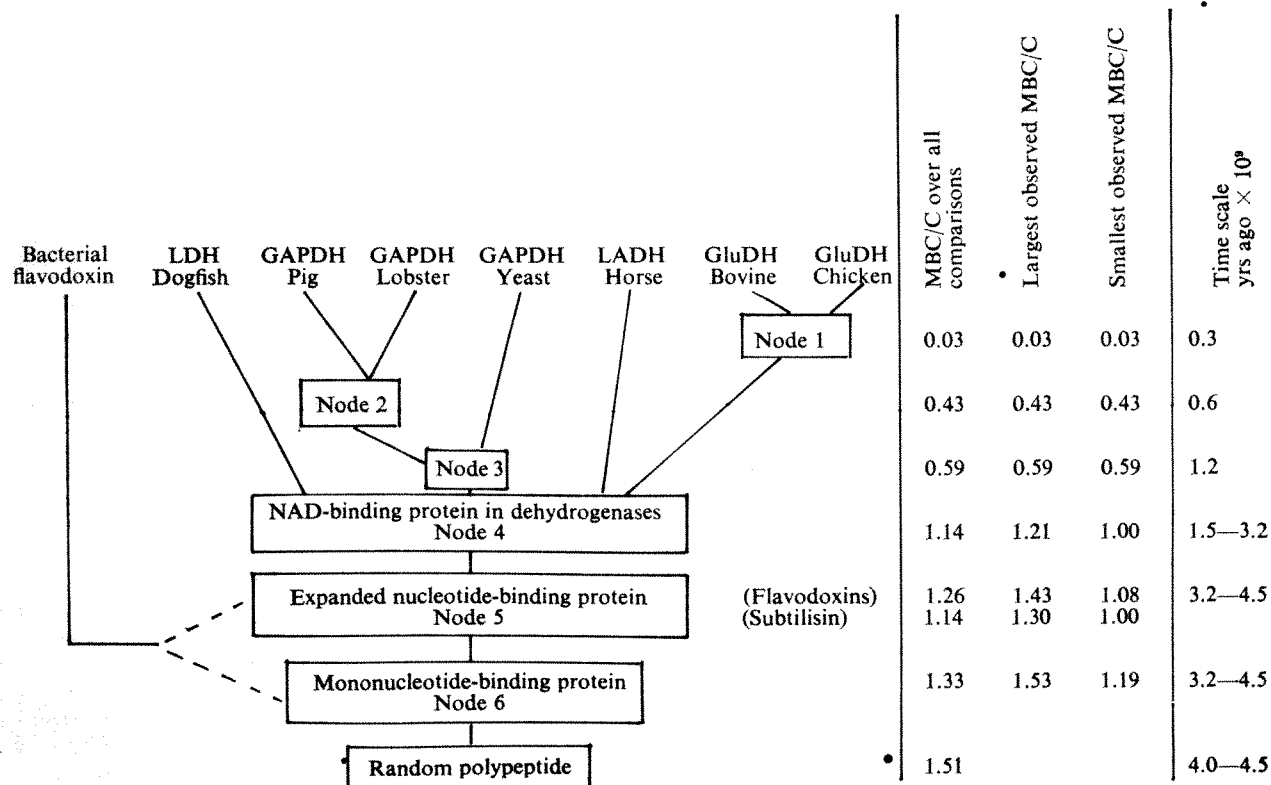

Fig. 6 Evolutionary tree consistent with observed minimum base changes per codon (MBC/C) and possible time scale derived primarily from fossil data.

C. I. Brändén, M. Beuhner, M. L. Hackert and W. Eventoff for important discussions and Sharon Wilder and Sandra Hurto for technical assistance. Three abundance classes in HeLa cell messenger RNA

J. O. Bishop, J. G. Morton, M. Rosbash & Melville Richardson

Department of Genetics, University of Edinburgh, West Mains Road, Edinburgh, EH9 3JN, UK

Approximately 35,000 different poly(A)-containing RNA sequences are present in HeLa cell cytoplasm. The sequences are grouped in three distinct abundance classes.

THE amount of DNA per haploid genome in the higher eukaryotes is known to be very large, and this has long posed the question of how much of the DNA encodes mRNA. Up to the present time few serious attempts have been made to answer this question. One problem has been the difficulty experienced in attaining sufficiently high concentrations of RNA to drive hybridisation reactions to completion. The discovery of poly(A) stretches in mRNA¹⁻³ has partially removed this difficulty, since poly(A)-containing RNA can now be separated from rRNA^{2,4,5} and much higher concentrations of mRNA can be attained. A second difficulty has been the existence of repetitive sequences in the DNA⁶: the transcript of one repetitive sequence can hybridise with related sequences,

producing falsely high results. This problem was solved by Hahn and Laird⁷ and others⁸⁻¹¹ using a technique devised by Kohne¹². Labelled nonrepetitive DNA sequences are isolated using hydroxyapatite, and annealed with an excess of unlabelled RNA. The DNA-RNA hybrids are then recovered on hydroxyapatite. In this way it was shown that about 10% of nonrepetitive mouse DNA was represented in transcripts found in total brain RNA^{7,9,10}. Similarly 0.9% of nonrepetitive *Xenopus* DNA is represented by transcripts in the mature oocyte⁸.

An even more serious problem has been that whatever answer was obtained, it had to be regarded as a minimum. No matter how much RNA was added, or for how long the samples were annealed, the possibility always remained that classes of RNA were present at a lower concentration than the least concentrated sequences observed to react. Such RNA sequences would fail to react significantly with the complementary DNA sequences, and would go undetected. This problem can now be solved in the following way. It is now possible to synthesise a complementary DNA

Fig. 1 Molecular weight distribution of HeLa cell mRNA. *a*, Sucrose gradient of enriched mRNA fraction showing A_{254} and results of annealing a portion of each fraction with poly(U)²¹(o). Sedimentation is from left to right. *b*, Cumulative plot of number of mRNA molecules against molecular weight (calculated according to Spirin²³ and Gierer²⁴). Two gradients like that shown in panel *a* were averaged. Approximately 10^9 HeLa cells were washed and lysed with RSB containing 1% NP-40. Nuclei were separated by centrifugation and the outer membrane fraction was removed²⁵ and added to the cytoplasmic fraction. Cytoplasmic RNA was extracted by a procedure²⁶ modified after Parish and Kirby²⁷ and passed repeatedly over oligo(dT)-cellulose⁴ until free of material which reacted with poly(U)²¹. The poly(A)-containing RNA was eluted⁴ and again treated in the same way. The final eluate from oligo(dT)-cellulose was centrifuged for 16 h at 25,000 r.p.m. and 25°C on a 15–30% sucrose gradient in NTE (0.1 M NaCl, 10 mM Tris, pH 7.5, 1 mM EDTA) containing 0.5% SLS (Spinco No. 27 rotor). The mRNA preparations used in this report were prepared by precipitating fractions between 5 and 35S with ethanol, and passing the precipitate, dissolved in 0.3 M NaCl–10 mM Na acetate, pH 5, over a column of Sephadex-SP50 overlying Chelex-100, developed with the same buffer.

transcript (cDNA) on a template of poly(A)-containing mRNA^{13–15}. By annealing this with an excess of the RNA template, we can determine the R_{ot} (product of initial RNA concentration and annealing time) at which the cDNA transcript hybridises completely. The same R_{ot} will be sufficient to obtain hybridisation of all the DNA complementary to mRNA when an excess of unlabelled mRNA is annealed with labelled single-copy DNA. Thus, in principle, the answer obtained should be a definitive one.

The availability of cDNA offers a second important advantage in that the kinetics of hybridisation between cDNA and an excess of unlabelled mRNA are dependent on the sequence complexity of the mRNA^{16,17}. By comparison with a suitable kinetic standard it should be possible to estimate the complexity of the mRNA in favourable cases. When this is so, we have available two independent estimates of mRNA sequence complexity. If they agree, confidence in the estimates will be greatly strengthened.

Preparation of HeLa cell mRNA

The mRNA was prepared by extracting the total cytoplasm of cells lysed with 1% NP-40. Thus, both free and membrane-bound polyribosomes contributed their mRNA populations, together with any mRNA present in the

postribosomal fraction. Poly(A)-containing RNA was prepared using oligo(dT)-cellulose⁴. The evidence at present available^{18,19} indicates that most mRNA contains poly(A). The great advantage of using this method is that it provides a defined, reproducible fraction of the total cellular RNA which is predominantly mRNA. Nevertheless, such preparations contain some 18S and 28S rRNA (Fig. 1). To accommodate this problem, we titrated each mRNA preparation with radioactive poly(U)^{20,21}. Two preparations of HeLa cell mRNA (containing rRNA) bound 8.4% and 8.6% by weight of poly(U). If we take the number-average molecular weight of the mRNA to be 640,000 (2,000 nucleotides) and the average length of the poly(A) to be 150 nucleotides²² the amount of poly(U) bound should be 7.5% by weight (the ribonuclease-resistant complex formed between poly(A) and poly(U) is a 1:1 complex²¹). In practice, we assumed a 10% by weight binding in calculating the mRNA concentration. Minor adjustments are made in the subsequent calculations.

The number-average molecular weight of the mRNA was estimated by annealing sucrose gradient fractions with radioactive poly(U) (Fig. 1). Assuming that poly(A) size is the same irrespective of the size of the mRNA, the number-average molecular weight is readily calculated to be close to 640,000.

Molecular hybridisation

Total HeLa cell mRNA proved to be as efficient as haemoglobin mRNA as a template for cDNA synthesis by avian myeloblastosis virus reverse transcriptase. The reaction was completely dependent upon priming by (pT)₁₀ suggesting that synthesis starts at the 3' ends of the mRNA molecules within the poly(A) sequence^{13–15}.

In vast DNA excess hybridisation experiments, labelled HeLa cell mRNA shows a prominent repetitive component (A. Spradling, S. Penman, S. Campo and J. O. Bishop, manuscript in preparation). To estimate the proportion of

repetitive sequences in the cDNA, it was annealed with an excess of unlabelled HeLa cell DNA. Highly labelled non-repetitive HeLa cell DNA was also annealed with unlabelled DNA to provide a comparison (Fig. 2). The non-repetitive cellular DNA behaved as though completely unique, with a $C_{0t\frac{1}{2}}$ of close to 10^3 mol s l^{-1} . The cDNA showed evidence of a 10% repetitive component. The $C_{0t\frac{1}{2}}$ of the second, major cDNA transition is also close to 10^3 mol s l^{-1} .

The hybridisation of the cDNA with an excess of mRNA (template) is shown in Figs 3 and 4. Figure 3 shows a linear-log plot of the data. Three transitions are seen, with midpoints ($R_0t\frac{1}{2}$, mol s l^{-1}), of 0.05, 0.9 and 45. That these are real is shown more clearly in Fig. 4. The linear-log plot tends to obscure the inflections between transitions which are more easily seen in straightforward linear plots. Three of these are needed to cover adequately the range of Fig. 3. Figure 4a shows the first inflection clearly, Fig. 4b shows both, and Fig. 4c shows the second clearly. Note the differences in the scale of the three abscissae of Fig. 4.

Fig. 2 Renaturation experiments with an excess of unlabelled HeLa cell DNA. The labelled species were (●) nonrepetitive HeLa cell DNA; (○) cDNA prepared against total cytoplasmic poly(A)-containing RNA; and (△) the fraction of nonrepetitive HeLa cell DNA which hybridises with mRNA at a R_0t of 350. cDNA was synthesised using as template mRNA prepared as described in Fig. 1 (ref. 28, except that the reverse transcriptase was purified through CM-Sephadex²⁹ and the substrate was ³H-dCTP (13.3 Ci mmol⁻¹)). HeLa cell DNA was purified as described³⁰, sheared at 50,000 p.s.i. in a Sorvall French Press at 10°–15° C in 0.3 M NaCl–10 mM Na acetate, pH 5, and passed over a Sephadex-SP-50-Chelex-100 column developed with the same buffer. DNA prepared in this way is 300–400 nucleotides long. Labelled DNA (2.4×10^5 cpm μg^{-1}) was prepared in the same way from cells labelled with ³H-thymidine. Nonrepetitive DNA was purified by annealing to a C_{0t} of 10 mol s l^{-1} and isolating the fraction eluting from hydroxyapatite between 0.12 M and 0.4 M PB (equimolar Na-phosphate buffer) at 65° C. DNA renaturation was carried out as described³¹, but using 0.24 M PEB (equimolar Na-phosphate buffer containing 1 mM EDTA) at 70° C. Samples were diluted to a final DNA concentration of 250–300 μg ml⁻¹ and divided into two aliquots, one of which was treated at 50° C for 40 min with nuclease S₁ (ref. 32) in a solution with the final composition: 48 mM PEB, 0.2 mM EDTA, 20 mM NaCl, 30 mM Na acetate, pH 4.5, 0.6 mM ZnSO₄, 0.052 N acetic acid.

Fig. 3 Hybridisation between cDNA and its mRNA template. Three experiments are shown, two (○) performed with mRNA from cells in spinner culture, one (●) with mRNA from a monolayer culture grown in burlers. In all, five reaction mixtures were used, containing 38, 43 and 295 μg ml⁻¹ (○) and 20 and 210 μg ml⁻¹ (●) of mRNA, assuming a 10% poly-(A) content. Samples were annealed at 70° C in 0.24M PEB and challenged with nuclease S₁ in the presence of 300 μg ml⁻¹ of denatured duck DNA (Fig. 2). The continuous line was drawn using the relationship

$$(d/D_0) = 1 - \sum P_n / e^{k_n t} P_n R_0$$

where D_0 and d represent respectively the initial amount of DNA and the amount duplexed at time t (s) and R_0 the amount of mRNA present (all in mol l^{-1}). The subscript n denotes the transition (1st, 2nd or 3rd). In each transition, P denotes the proportion of the cDNA represented, and k the rate constant of DNA–RNA hybridisation (1 mol⁻¹ s⁻¹), given by $k = 0.69/R_0t_{1/2}$ (ref. 33). The values taken for the first, second and third transitions were: P , 0.22, 0.28, 0.50; k , 62.7, 2.74, 0.307.

The interpretation of the hybridisation data depends on the availability of a suitable standard. This is provided by the work of N. D. Hastie, M. G. Ferace, K. B. Freeman and J. O. Bishop (unpublished). The $R_0t\frac{1}{2}$ of the transition observed when an excess of rabbit haemoglobin α -chain mRNA is annealed with homologous cDNA is 3×10^{-4} mol s l^{-1} . When total ($\alpha + \beta$) haemoglobin mRNA is annealed with homologous cDNA, the $R_0t\frac{1}{2}$ is 6×10^{-4} mol s l^{-1} . Since the molecular weight of haemoglobin mRNA is about 200,000 (refs 34, 35) we take 9×10^{-4} mol s l^{-1} to be the $R_0t\frac{1}{2}$ of an RNA with a molecular weight of 6×10^5 .

The data which can be extracted from Fig. 3 are shown in Table 1. The proportion of the cDNA which reacts in each of the three transitions is shown in the first column, and the observed $R_0t\frac{1}{2}$ of each in the second. The line shown in Fig. 3 was drawn by summing three ideal first order reactions calculated according to these characteristics. The good fit of the line to the data indicates that it is reasonable to interpret each of the transitions as an

Table 1 Numerical analysis of the data shown in Figs. 3 and 4

Transition	<i>P</i>	$R_{ot\frac{1}{2}}$ (observed)	$R_{ot\frac{1}{2}}$ (if pure)	No. of 640,000 dalton sequences		Molecules of each sequence per cell
				If 90% saturation	If 100% saturation	
1	0.22	0.05	0.015	17	15	8,000
2	0.28	0.90	0.335	370	330	440
3	0.50	45	29.9	33,000	36,250	8

For the definition of *P* see Fig. 3.

ideal pseudo-first-order reaction. (The reaction is pseudo-first- rather than second-order because the RNA is in great excess over the cDNA). If the RNA responsible for any one transition were present on its own, thus contributing all of the RNA used in calculating R_{ot} , the $R_{ot\frac{1}{2}}$ of its transition would be lower. The values of $R_{ot\frac{1}{2}}$ have also been corrected for the 7.5% poly(A) content of mRNA (Table 1, column 3). The numbers of sequences of average molecular weight 640,000 required to generate the three transitions are obtained by dividing the corrected $R_{ot\frac{1}{2}}$ values by 9×10^{-4} (Table 1, column 4). Interpreting Table 1, we would say that HeLa cell poly(A)-containing cytoplasmic RNA contains three distinct fractions: 22% of the RNA comprises only 17 different sequences, 28% comprises 370, and 50% comprises 33,000 different sequences, a total of close to 35,000 sequences. Some qualification is necessary because of the small amount of repetitive sequence found in the cDNA

(Fig. 2) which may contribute disproportionately to the first or second of the transitions seen in Fig. 3. This could affect the absolute value in one case by a factor of 1/3 at the very most.

These numbers were derived by assuming that no more than 90% of the cDNA can form hybrids, as they are measured here. This is true for cDNA prepared against haemoglobin mRNA, where it can be convincingly demonstrated. If the theoretical upper limit were 100%, the numbers would not change greatly (Table 1, column 5). Of course, in the case of any of the transitions, the number-average molecular weight of the RNA molecules need not be exactly 640,000. If so, the calculations would require some adjustment.

The data can also be used to calculate the numbers of copies per cell for RNA sequences of each class. By analogy with complex DNA renaturation patterns⁶ we see that these depend on the observed $R_{ot\frac{1}{2}}$ but not upon either RNA molecular weight or the percentage of the total reaction which each transition occupies. Taking 10^6 HeLa cells to contain 12.5 μ g of RNA of which 5% is poly(A)-containing mRNA, the number of copies per cell equals 400 (observed $R_{ot\frac{1}{2}}$). Thus (Table 1, column 6) there are on average 8,000 RNA copies per cell in the highest frequency class, and about 9 copies per cell in the lowest.

A total of 35,000 RNA sequences of average molecular weight 640,000 represents a total sequence complexity of 2.2×10^{10} daltons. Approximately 20% of the HeLa cell mRNA (prepared in the same way) is repetitive (A. Spradling, S. Penman, M. S. Campo and J. O. Bishop, manuscript in preparation). Accordingly, the overall complexity of the non-repetitive sequences in the mRNA is about 1.8×10^{10} daltons. The analytical complexity of mammalian DNA is 1.8×10^{12} daltons, and of this about 70% or 1.3×10^{13} daltons is non-repetitive. Thus, the cDNA hybridisation kinetic data predict that 1.4% of 'single-copy' HeLa cell DNA is complementary to our mRNA preparation.

Sheared, purified single-copy DNA, highly labelled with ³H-thymidine, was annealed with enriched mRNA and the double-stranded fraction, containing both DNA-RNA hybrid and DNA duplex, was isolated using hydroxyapatite (HAP). This fraction was dialysed against a low-salt buffer, digested exhaustively with ribonuclease and again fractionated on HAP. This moves the DNA which was hybridised with RNA into the single-strand fraction, while leaving duplexed DNA in the double-strand fraction¹². The results of two such experiments are shown in Table 2. The average of these is 1.05%, in good agreement with prediction. In one experiment the single-copy DNA complementary to mRNA was recovered from the second HAP column and annealed with an excess of unlabelled HeLa cell DNA. Although it failed to renature completely, presumably due to degradation during the very extensive handling it experienced, this fraction clearly did not contain repetitive DNA sequences (Fig. 2).

Number of mRNA species in HeLa cells

One source of uncertainty which remains is the possibility that different mRNA species are not equally transcribed by reverse transcriptase. This is not, however, so serious

Fig. 4 Linear plots of hybridisation between cDNA and its mRNA template. The data are the same as for the linear-log plot shown in Fig. 3. Dotted lines indicate inflections between transitions.

as might be thought at first sight. Provided that the three frequency classes were transcribed with similar efficiency, even though that efficiency were low, the $R_{ot}^{1/2}$ values would be approximately correct, since they depend on the overall mRNA concentration. If an entire frequency class of mRNA molecules were not transcribed, and if this were the lowest frequency class (in terms of mRNA molecules per cell) the cDNA data would be misleading. This possibility is, however, extremely unlikely. A lower frequency class of RNA molecules which formed a significant proportion of the total would necessarily be complementary to a large part of the single-copy DNA. The good agreement between the kinetic data and the DNA saturation experiments virtually excludes the possibility that such a fraction exists.

Recently, Grady and Campbell³⁷ found that 8.5% of mouse single-copy DNA would form duplexes with total RNA from a mouse cell line, while 15% formed duplexes with RNA from the same line transformed with polyoma. Using a double-reciprocal method to extrapolate the reactions to completion, they estimated that the respective RNA preparations were complementary to about 20% and 30% of the single-copy DNA. If most of the complexity of total cellular RNA is due to HnRNA, the difference between their values and ours is compatible with current ideas on the processing of HnRNA³⁸.

We cannot be sure that all of the poly(A)-containing sequences we have studied are in fact mRNA sequences, although the literature on the subject points strongly in this direction. Assuming that they are, the number 35,000 is much greater than the number of 'genes' estimated by genetic means to be present in the genome of *Drosophila* (for example refs 39–41) and on the same order as the number of protein-encoding sequences estimated by Ohta and Kimura⁴² to be present in the human genome. As far as the human situation is concerned, we may consider three alternative possibilities. (1) HeLa cells may be completely or almost completely derepressed, expressing most of the potential of the human genome. (2) The total potential of the genome may be much greater than suspected, and HeLa cells express only a minor part of it. (3) Human cells have a large number of common functions, and differences between them are determined by relatively few mRNA species: HeLa cells therefore contain the common sequences as a large proportion of their total mRNA population. The answer to these questions will no doubt come from further work of a similar nature with HnRNA and mRNA from cell lines and from tissues.

The different frequency classes of mRNA offer interesting grounds for speculation. In this laboratory, M. S. Campo has obtained evidence which strongly suggests that a small proportion of rat myoblast mRNA contains a high proportion of repetitive sequences. Some of the mRNA

in the higher abundance (molecules per cell) classes may therefore be transcribed from repetitive genes, comparable to histone genes^{43,44}. In HeLa cells, two mRNA populations with different half lives have been described^{45,46}. The more abundant classes of mRNA discovered here may belong to the longer-lived class of mRNA. Lastly, as to function, there are obvious candidates in the protein structure of the cell for more abundant mRNA species, such as actin, tubulin and fibrin, which are present in large amounts in exponentially growing cells, and therefore are very probably synthesised from relatively abundant species of mRNA.

This work was supported by grants from the Cancer Research Campaign and the Science Research Council. We thank Dr J. W. Beard, Duke University, Durham, N.C., for supplying us with avian myeloblastosis virus.

By applying the same techniques to a *Drosophila melanogaster* cell line (Schneider line 3) we find that it contains a much smaller number of cytoplasmic poly(A)-containing RNA sequences, of the order of 4,000 (M. Izquierdo and J. O. Bishop, unpublished experiments).

Table 2 Complementarity between nonrepetitive HeLa cell DNA and enriched mRNA

Exp.	R_{ot} (mRNA)	C_{ot} (DNA)	Percentage of total DNA recovered	
			Duplex fraction (First fractionation)	Single-strand fraction (Second fractionation)
1	335	8	4.5	1.2
2	360	8	5.2	0.9

Nonrepetitive HeLa cell DNA was prepared by annealing highly labelled (150,000 c.p.m. μg^{-1}) sheared DNA to a C_{ot} of 10 mol s^{-1} and fractionating by means of hydroxyapatite (HAP)³⁶. Aliquots were annealed with mRNA at 70° C in 0.24 M PEB, diluted to 0.02 M PB and adsorbed to HAP. The duplex fraction was eluted between 0.12 and 0.4 M PB. This was dialysed exhaustively against 10 mM tris, pH 7.5, and then digested for 2 h at 37° C with 20 $\mu\text{g ml}^{-1}$ of RNase. The sample was then adjusted to 0.02 M PB and the fractionation was repeated. The single-stranded fraction was eluted between 0.02 and 0.12 M PB.

Ultraviolet spectra of Capella

IN December 1973, during observations from the space observatory Orion 2 on Soyuz 13, three spectrograms of Capella (α Aur, GO III, $m_v=0.2$) were obtained in the wavelength region 2,000-3,000 Å. The spectrograms were made by a wide-angle meniscus telescope of the Cassesgrain system, with an aperture diameter of 240 mm, an equivalent focal length of 1,000 mm, and a 4-grade quartz prism objective. The dispersion of the spectrograph was 170, 280 and 550 Å mm⁻¹, at wavelengths of 2,000, 2,500 and 3,000 Å, respectively.

Spectrograms of the Capella were obtained from exposure times of 15 s (film F-19), 1.5 min (F-20), and 18 min (F-21) (Fig. 1). Even the spectrogram with an

exposure time of 15 s at wavelengths of 2,700-5,000 Å was overexposed. Increasing the exposure time resulted in an extension of the photographic background on the film at the expense of faint stars. This accounts for a regular diminution of the mean photometric amplitude between the background of the film and the darkness, passing from the F-19 record over to the F-21 record.

At spectral resolutions of 8, 14 and 28 Å at wavelengths of 2,000, 2,500, and 3,000 Å, respectively, the Orion 2 spectrograms were originally to be used only for a study of the continuous spectra of stars. Often the quality of the spectrograms, however, proved so satisfactory that stronger

Fig. 1 Microphotometric records of the three ultraviolet spectrograms: a, 15s (F-19 film); b, 1.5 min (F-20 film); c, 18 min (F-21 film). All wavelengths identified in Table 1. 1-10 as in Table 2.

Table 1 Ultraviolet absorption lines in the spectra of Capella

Observed length (Å)	Proposed identification		
2,852	2,851.6 MgI	2,852.2 MgI	2,851.8 FeI
2,800	2,795.5 MgII	2,802.7 MgII	
2,570	2,570.8 FeII	2,571.0 TiII	
2,470	2,470.7 FeII		
2,365	2,364.8 FeI	MoII	NiII
2,315	2,316.0 NiII	2,316.0 TiII	2,315.6 MoII
2,285	2,286.2 CoII	2,284.1 FeII	2,284.8 CoII
2,270	2,270.2 NiI		
2,250	2,251.2 SnI	FeII	TiII
2,235	2,236.3 CuI	MoII	FeII
2,180	2,180.5 NiII		
2,150	2,148.7 SnI	2,152.2 SnII	FeII

absorption lines or bands could be distinguished. This was the case with the spectrograms of Capella.

The continuous spectrum of Capella extends to about 2,100 Å (Fig. 1). In the interval 2,850-2,150 Å, nearly 10 absorption lines (bands) can be distinguished with certainty (Fig. 1, and Table 1). Strictly speaking, each of these 'lines' is a band resulting from the blending of contiguous absorption lines. There is some doubt about the reality of line 2,150 Å, although it occurs with enough certainty, simultaneously on F-19 and F-20 film.

Moreover, about 10 absorption lines can be marked out less confidently (Fig. 1 and Table 2). In fact, however, the true number of measurable absorption lines exceeds those indicated in both Tables, especially in the region shorter

Table 2 Ultraviolet lines in the spectra of Capella

No. of line in Fig. 1	Observed length (Å)	Proposed identification		
1	2,640	TiII	FeII	
2	2,610	FeII	NiII	
3	2,540	FeI		
4	2,510	FeI	NiI	
5	2,490	FeI		
6	2,440	FeI	MgII	TiII
7	2,405	NiII	MoII	FeII
8	2,385	FeII	MoII	
9	2,365	MoII		CuII
10	2,345	FeII	NiII	

than 2,300 Å. In some cases even the weak line is distinctly visible in all three spectrograms (although using F-21 film) at wavelengths shorter than 2,250 Å, the short-wave tail is veiled by diffuse light and by the field from Capella itself.

The final location of such lines, however, must await a more thorough examination.

At the wavelengths under consideration (2,800–2,150 Å) the absorption lines in the spectrum of Capella pertain largely to the neutral metals and their ions, which have ionisation potentials of less than 8 eV. These are: FeII, NiII, CuII, MgII, TiII, SnII, SiII, MoII, MnII, and so on.

The 'elevation' in the continuous spectrum at 2,350–2,430 Å, is clearly seen on F-20 film, less clearly seen on F-21 film and only partly seen on F-19 film (Fig. 1). It is unlikely that the elevation results from a blending of the emission lines; rather, it simply forms part of the continuous spectrum. This must lead to the conclusion that there is a large zone of depression on both sides of the elevation, extending to nearly 2,700 Å from the long-wave side, and to 2,100 Å from the shortwave side. Future observations will show whether this conclusion is correct.

A more detailed analysis of the spectrograms will be discussed elsewhere.

I thank R. Kh. Ohanessyan for help in taking the microphotometric records.

Faraday rotation studies in Africa during the solar eclipse of June 30, 1973

Four stations were set up in southern and eastern Africa (Table 1) to observe variations of total electron content during the eclipse of the Sun on June 30, 1973. Each station was equipped with a conventional Faraday rotation recording system consisting of a receiver and a mechanically rotating aerial. We recorded the amplitude fading of the 137 MHz signals from the geostationary satellite, Intelsat IIF3, located at approximately 14°W. The four stations were operating for a total period of 10 d, including June 30, the day of the eclipse.

Chimonas and Hines¹ first suggested that internal atmospheric gravity waves should be generated as a result of the Moon's shadow travelling with supersonic speed during an eclipse of the Sun. In the case of the solar eclipse of March 7, 1970 they suggested that the magnitude of the pressure perturbation would be as much as 10% at an

Fig. 1 The variation of the Faraday rotation angle of the 137 MHz transmission received from Intelsat IIF3 at four stations in eastern and southern Africa during the eclipse of June 30, 1973. *a*, Start of the eclipse; *b*, maximum phase of the eclipse; *c*, end of the eclipse.

altitude of 200 km. Davis and da Rosa² observed fluctuations of 1.5% in total electron content on signals from two geostationary satellites, which they tentatively associated with the eclipse. Other workers^{3,4} also observed ionospheric disturbances at times approximately appropriate for eclipse generation. Frost and Clark⁵ conclude that there is insufficient evidence to associate the observations positively with the eclipse. Beer and May⁶ computed the expected paths of bow waves generated by the solar eclipse of June 30, 1973 and concluded that the waves would come to a focus in southern Africa. It had been estimated⁷ that in the region associated with this focusing, the bow wave amplitude should be at least 10 times greater than in California in 1970.

During the 1970 eclipse the directions of the bow waves,

Table 1 Stations established in Africa during the 1973 eclipse

	Station coordinates		Coordinates of the ionospheric point	
	Latitude	Longitude	Latitude	Longitude
Nairobi	1.3° S	36.8° E	1.2° S	32.3° E
Dar es Salaam	6.8° S	39.2° E	6.3° S	34.2° E
Blantyre	15.8° S	35.0° E	14.7° S	30.4° E
Grahamstown	33.3° S	26.7° E	22.2° S	30.8° E

Fig. 2 The raw data after filtering to remove long period changes in the total electron content. The filtered data are shown for a band pass of 5–45 min.

with respect to the local magnetic fields and the radio signal paths, were not so favourable for the observation of travelling ionospheric disturbances induced by the eclipse as in 1973. The greater ionospheric coupling in 1973, and the long duration of the eclipse, encouraged expectations of perturbations of the total electron content of at least 15%.

The positions of the ionospheric points have been calculated for an ionospheric height of 350 km. The Faraday rotation records were read at intervals of 1 min. Totality in East Africa occurred at about 1300 UT, and the estimated time of arrival of the bow wave^{5,6} near Grahamstown was 1500–1700 UT. The expected perturbation of some 15% in the total electron content at Grahamstown could easily have been recorded. The observations, however, show no fluctuations identifiable with the eclipse at any of the four stations (Fig. 1). These results agree with the observations of Schödel *et al.*⁷

The raw data have been filtered to reduce noise and to remove the long period changes (mainly diurnal) in the total electron content (Fig. 2). The results show that travelling ionospheric disturbances with amplitudes of 3% were frequent at Grahamstown; there was, however, no way of associating perturbations on the records with the eclipse at any of the four stations. We conclude that if there were any travelling ionospheric disturbances, induced by the eclipse, they produced variations of less than 1% in the total electron content. Thus, it seems that the disturbances were very much smaller than had been anticipated.

The failure to observe eclipse induced fluctuations of the total electron content under such apparently favourable conditions must raise doubts about the validity of the theories which predict them, and about the interpretation of previous observations. In this connection, we draw attention to the suggestion of Beer^{6,8} concerning the production of travelling ionospheric disturbances by the terminator travelling at supersonic speed. Titheridge⁹ rarely observed travelling ionospheric disturbances associated with sunrise and sunset.

The times of maximum eclipse and of the beginning and end of the eclipse have been computed by the Nautical Almanac Office for a height of 350 km at the ionospheric points corresponding to the stations at Nairobi, Dar es Salaam and Blantyre. The time delay between the local maximum of the eclipse and the subsequent minimum in the electron content was about 5 min at Nairobi—much shorter than expected. At Dar es Salaam and Blantyre it was around 20 min, which agrees with earlier observations

elsewhere. Klobuchar *et al.*¹⁰ also observed a delay of only 5 min between the minimum in the electron content and the local time of maximum solar observation at Akjoujt (20.1°N, 14.0°W) during the 1973 eclipse. Nairobi and Akjoujt are situated at about 10° on either side of the geomeric dip equator in Africa.

We thank Mr F. Gardiner for help with the arrangements at the Physics Department, University of Dar es Salaam, Professors A. K. Som and E. E. Baart in the Physics Departments of the Universities of Malawi and Rhodes, respectively, for their assistance, and Mr F. J. Watson of the Royal Greenwich Observatory for the computation of the eclipse times. The experiment was assisted by a United States Air Force grant, and by a grant from the Royal Society.

Liquid immiscibility between silicate and carbonate melts in naturally occurring ijolite magma

PORTIONS of the fluids and melts responsible for the crystallisation of rocks and minerals may be trapped and preserved as small inclusions within a crystal, providing much information about the physical and chemical conditions prevailing during crystallisation^{1,2}.

Studies of inclusions in apatites from some East African carbonatites and ijolites³ reveal that carbonate-rich and silicate-rich melts can coexist as immiscible fractions in naturally occurring ijolite magmas. The apatites come from ijolite pegmatites collected from two localities within the Usaki complex of West Kenya⁴. The distinction between primary inclusions (those formed during the actual growth of the crystal) and secondary inclusions (those formed after growth has terminated) was immediately apparent since the primary inclusions characteristically occur as long (up to 150 μm) tubular cavities parallel with the *c* axis of the apatite crystal. Only rarely were small, curved planes of minute (<10 μm) secondary inclusions observed.

Four different primary inclusion types were recognised in the apatites from ijolite pegmatite (U366);

Fig. 1 Large, tubular, multisolid, carbonate-rich inclusion (type A) in apatite from ijolite U366. Most of the colourless, crystalline material within the inclusion exhibit high order interference colours. On the right of the inclusion, several small, black, magnetic, crystalline phases are apparent. Bar = 20 μm .

- (1) Silicate melt inclusions consisting of minute, crystalline specks in a glassy matrix ($n \sim 1.55$) but no vapour bubble.
- (2) Carbonate-rich melt inclusions which consist of at least 60% anisotropic, colourless, crystalline material (Fig. 1) and usually a small amount of aqueous fluid and vapour. This colourless material reacted instantly, dissolving with rapid effervescence, when the inclusions were opened in dilute, acidified (HCl) glycerol on a microscope crushing stage of the type described by Roedder⁵. Most of this material, however, remained insoluble in pure deionised water. This behaviour in acid media and the high order interference colours of these crystals indicate that they are carbonate-bearing minerals. Small crystals of a black, opaque, magnetic ore mineral are also commonly present.
- (3) Nahcolite-bearing inclusions which represent a trapped aqueous fluid phase. These inclusions contain variable amounts of Nahcolite (NaHCO_3 , ref. 6) aqueous fluid, and a CO_2 -rich vapour bubble.
- (4) Gaseous inclusions representative of a vapour phase. These consist almost entirely of highly compressed (sometimes liquefied) carbon dioxide.

In many instances, all four inclusion types occur side by side in the same apatite crystal. Since they are primary³, they represent low temperature equivalents of the trapped portions of phases present in the ijolite magma during the crystallisation of the apatites.

The apatites from ijolite pegmatite (U1256) also contain

Fig. 2 Complex carbonate-rich/silicate melt inclusion in apatite from ijolite U1256. This inclusion shows a dark, central patch of brown, green and black crystalline phases; predominantly silicate minerals (silic.). The colourless solids are principally carbonate-bearing phases (carb.). Bar = 20 μm .

Fig. 3 The behaviour of the contents of a complex, multi-solid carbonate-rich/silicate melt inclusions on heating (type B from U1256). Bar = 20 μm . a, At 23° C, the inclusion as seen at room temperature. Note the presence of a large vapour bubble (V); b, At 565° C, melting of the carbonate phase begins; c, At 890° C, all the carbonates have melted to a colourless liquid. Small globules of a clear green liquid (one of which is arrowed) have also formed from the dark silicate minerals. Thus, two immiscible liquids are present in the inclusion at this temperature; d, At 960° C, complete homogenisation of the carbonate-rich melt and silicate melt has taken place. The vapour bubble, although somewhat smaller in volume, still remains.

silicate inclusions (glassy matrix, $n \sim 1.56$) and carbonate-rich inclusions, but very few of the aqueous, nahcolite-bearing or gaseous inclusion-types. A further type has, however, been recognised in this sample (Fig. 2). These inclusions are intermediate between carbonate melt inclusions and silicate melt inclusions, and consist of various proportions of both silicate and carbonate-rich material. Whereas the individual silicate inclusions and carbonate inclusions represent the separate trapped portions of two distinctly different melts, the complex silico-carbonate inclusions result from the simultaneous entrapping of a portion of carbonate-rich melt and silicate-rich melt. This demonstrates that these two melts coexisted in the ijolite magma as separate phases at the time the apatites crystallised. Heating studies were made on the inclusions using a Leitz 1350 microscope heating stage. The details will be published elsewhere but it is interesting to note the behaviour of the complex silicate/carbonate-rich melt inclusions as they are heated and cooled. Two immiscible liquids were observed at elevated temperatures (Fig. 3c).

When simple carbonate-rich melt inclusions (here called type A) from both samples were heated (U366 and U1256), their crystalline, carbonate-bearing mineral phases began to melt at about 500° C and were almost entirely molten at temperatures between 640° and 750° C. At these temperatures, only a small amount of solid material, including the small, black, opaque, magnetic, crystalline speck, remained together with a small vapour bubble. These phases usually dissolved in the melt at higher temperatures. On cooling, the inclusion contents recrystallised completely and even rapid cooling failed to produce a glass. When the complex silico-carbonate-rich inclusions from U1256 were heated (Fig. 3), however, the colourless, carbonate-rich fraction melted at temperatures between 575° and 640° C but the silicate fraction, seen as small optically isotropic and anisotropic, green, brown and black patches within the inclusion, did not dissolve completely in the resulting melt. Instead, they melted independently to form pale green coloured globules at temperatures between 820° and 900° C. Where these globules occupied up to 20% of the total volume of the inclusions (type B), they gradually dissolved in the carbonate-rich melt at temperatures ranging from about 950° C up to 1,100° C. But in those instances where the globules occupied a volume greater than about 20% (type C), they still remained, coexisting with the carbonate-rich melt, even at 1,100° C (the maximum temperature attainable on the apparatus).

When inclusions of type B were cooled from the temperature at which the two melts had become miscible, the molten contents separated into two distinct immiscible liquid phases; green silicate globules and a carbonate-rich melt (Fig. 4). Continued cooling caused a small portion of the silicate globules to crystallise but most quenched to a pale green-coloured, isotropic glass. The colourless, carbonate-rich melt crystallised at temperatures between about 575° and 500° C.

Cooling of inclusions of type C gave similar results and some of the silicate globules were seen to coalesce into larger globules which subsequently quenched to a glass.

Heating studies on simple silicate melt inclusions were generally unsuccessful owing to leakage. When two small inclusions were heated to 950° C, then cooled, their contents were, however, seen under oil immersion to have quenched to the same pale green-coloured, isotropic glass as the green globules in the complex inclusions.

The exact composition of the two immiscible melts is unknown, but one is certainly a silicate-rich melt and the other carbonate-rich. Other phases such as CO₂ vapour and an aqueous, saline, carbonate-bearing fluid (seen as nahcolite-bearing aqueous inclusions) coexisted with these two melts in the ijolite magma.

Several authors⁷⁻⁹ have suggested that immiscibility may

Fig. 4 The behaviour of the contents of the inclusion shown in Fig. 3d, as it is cooled from 960° C. Bar = 20 μ m. a, At 950° C, initial separation (unmixing) of the homogeneous melt takes place. Silicate melt globules (one of which is arrowed) form, leaving a predominantly carbonate-rich melt; b, At 910° C, the silicate globules grow in size and unmixing of the two melts is almost complete; c, At 805° C, some of the silicate globules have coalesced, others begin to crystallise; d, At 575° C, the onset of crystallisation of the carbonate-rich melt (arrowed). The silicate globules have already crystallised or quenched to a glass.

be an important process in the derivation of carbonatitic fluids from parent carbonated silicate magmas. Experimental studies by Koster van Groos and Wyllie¹⁰⁻¹² on selected joins in the system $\text{CaO}-\text{Na}_2\text{O}-\text{Al}_2\text{O}_3-\text{SiO}_2-\text{CO}_2-\text{H}_2\text{O}$ at higher temperatures have confirmed the existence of immiscibility between carbonate-rich and silicate-rich melts in soda-rich synthetic systems, though it does not appear in more lime-rich systems¹³. Since the inclusions studied here represent trapped portions of a natural magmatic system, it is evident that immiscibility between carbonate-rich melts or fluids, and silicate melts can take place in natural ijolitic magmas. These data may be interpreted to show two different possible relationships between carbonatitic and ijolitic melts. First, a parental ijolite magma can, by immiscibility differentiation, produce carbonatite and silicate (?nepheline-syenite) partner magmas; or second, a hyperalkaline silicate parent magma can produce immiscible carbonatite and ijolite partner magmas. The former provides the simplest solution but we believe the field evidence indicates the latter.

Fig. 1 Transmitted light photograph ($\times 96$) of glass-kaersutite contacts from nodule 1718, Volcan de Tenequia. Kaersutite showing rounded margins is on the left, clinopyroxene is on the right. The glass contains a few microlites and minor olivine. The white areas are gas vesicles.

Nodules containing kaersutite, from the Volcan de Tenequia eruption of 1971, were collected on the southern tip of La Palma, Canary Islands. The wehrlite nodules are seldom greater than 10 cm in the largest dimension, are generally ovoid in shape, and consist of olivine (Fo_{80}), clinopyroxene, opaques and kaersutite. The most notable feature of the nodules is the presence of glass in amounts of 1–5% in several of the nodules. The glass is invariably associated with kaersutite and is highly vesiculated. Petrographic examinations show that the glass is not contamination from associated lavas. The glass-kaersutite relationships are shown in Figs 1 and 2. Melting of kaersutite is indicated clearly by both the rounded edges of the amphibole (Fig. 1) and the cusped shape of kaersutite margins in contact with the glass (Fig. 2). Occasionally, glass is present along olivine-kaersutite margins. Clinopyroxene shows no evidence of involvement in the melting event. Olivine (Fo_{80}) and very small amounts of clinopyroxene have crystallised from the melt, and are clearly distinguishable from the cumulate phases, both in composition and appearance (Fig. 2). The melting seems to be congruent.

Compositions of kaersutite and glass were determined by microprobe analysis of two separate nodules (Table 1). Compared with kaersutite, the glass is enriched in alkalis and alumina, is slightly enriched in silica, and is strongly depleted in magnesia. Iron, titanium, and calcium values are comparable. The compositional differences can only be attributed to the crystallisation of olivine and pyroxene from the melt.

We propose that the melting relationships shown here represent a model for the production of alkali basaltic magma through the melting of kaersutitic amphibole at depth. An important factor in this proposal is the striking similarity in compositions between kaersutites and alkali basalts. This is particularly true when comparing kaersutites to ankaramitic

Kaersutite is a possible source of alkali olivine basalts

STUDIES into the origin of basaltic magmas have led to the belief that the upper mantle contains a hydrous phase, either phlogopite or amphibole, as a source of water and potassium¹⁻³. Here we present data concerning the role of kaersutite, a possible upper mantle phase, in the genesis of alkali basalts. Specifically, we have observed the melting of kaersutite within ultramafic nodules from La Palma. Both the kaersutite and the glass produced through melting show strong compositional similarities to members of the alkali olivine basalt series. The observed relationships strongly indicate that alkali basalts may be derived from a melting event in which kaersutite is the principal participant.

Fig. 2 Transmitted light photograph ($\times 96$) of kaersutite (top), with a cusped shaped margin in contact with glass. A large olivine crystal with a glass inclusion at its centre is at the left. The small equant grains are clinopyroxene. The white area (lower right) is a gas vesicle.

rocks (Table 1) which may represent a parental magma for the alkali basalt series. Ankaramites are characterised by a relatively high K_2O content of $<1-2\%$ with a SiO_2 content of $41-44\%$. Kaersutites, usually noted for a high TiO_2 content, typically have K_2O abundances of $1-2\%$, a value substantially higher than in other aluminous amphiboles.

The observed differences in alumina, magnesia and alkali contents between kaersutite and the associated glass, lie within the variation of rock chemistry shown in the alkali basalt series. Differentiation trends are marked by a rapid decrease in MgO ,

Table 1 Chemical compositions of kaersutite and glass

with increases in Al_2O_3 and total alkalis at essentially constant levels of SiO_2 , TiO_2 , FeO and CaO at least to the basanite stage. The glass compositions closely approximate those of basanites (Table 1). As the glass composition is apparently controlled by the crystallisation of olivine, basalt compositions between ankaramites and basanites could easily be produced by fractional crystallisation of this mineral.

There is no evidence that the observed glass-kaersutite relationship actually represents melting of a hydrous phase at depth. Glass has been observed previously in ultramafic inclusions, and has been attributed to incipient fusion of the xenolith immediately before eruption^{4,5}. Similarly, the composition of the cumulate olivine does not indicate a mantle origin. Although the observed melting may, however, have occurred at shallow depths, it is reasonably certain that, compared with likely mantle assemblages, kaersutite would remain the mineral with the lowest melting temperature at depth (ref. 2).

The origin of kaersutites in ultramafic nodules has been generally attributed to the crystallisation of this mineral from alkali basalt magmas under hydrous conditions. It is entirely possible, however, that kaersutite is formed as a product of tholeiitic magmatism as well. Helz⁶ has shown that at $1,000^\circ C$ and $5 K_b PH_2O$, amphibole crystallising from a tholeiitic liquid contains 4.27% of TiO_2 and is comparable in composition to most reported kaersutites. Thus, a widespread kaersutite occurrence may result from the crystallisation and accumulation of the amphibole under hydrous conditions at midoceanic ridges or any site of tholeiitic activity. Gravitational settling of kaersutite may provide a zone enriched in amphibole which could then act as a reservoir for alkali olivine basalt production. At the ridge, melting of some of the stored amphibole, at temperatures in excess of those required for the production of tholeiitic liquids, would account for late-stage alkaline activity. If accumulation has resulted from crystallisation at midoceanic ridges, the lithosphere thus produced would contain at its base a potential source for alkali olivine magma over a large geographic area. Passage of the plate over a 'hot spot' could account for oceanic volcanism at sites far removed from ridges.

Previous arguments for the involvement of amphibole in the generation of basaltic magmas have been based on compositional similarities to basalts⁷⁻⁹, the requirement for a source of potassium¹, titanium⁸, and water, and experimental evidence from whole-rock melting experiments in the presence of vapour^{2,3}. The data presented here strongly suggest that kaersutite is entirely suitable as the principal source of alkali olivine basalts.

Elastic energy and plate tectonics

A GLOBAL, quadrupolar mechanical analysis of the energy stored in the Earth, based on the concept of a 'reference elastic distortion'^{1,2}, has shown that quadrupolar continental drift, and in particular the westerly polar motion could be understood as resulting from a yielding process which operates as a consequence of the elastic energy in the Earth.

Reduction of elastic energy is, however, not the only driving force available for continental drift; thermal stresses and thermal convection certainly play an important role³. Nevertheless, it is instructive to study the extent to which the elastic energy reduction principle alone can explain the finer details of continental drift. We here give a preliminary report of the calculations which have been made; a more extended account will be published elsewhere.

We have utilised various spherical harmonic analyses of the terrestrial topography⁴⁻⁶ and have taken density fluctuations into account by various degrees of quenching or total vanishing of g fluctuations. The gross features of our results were influenced very little by these effective isostatic compensations. To make things as simple as possible, we have also ignored compressibility and any radial variation of the density ρ or rigidity μ ; these, too, do not seem to alter appreciably our qualitative results, which show a significant correlation between regions of high elastic energy density and regions known to be seismically active. The predicted surface displacements are also in good agreement with accepted directions of continental drift.

The equations for self-gravitating elastic bodies⁷, have a local elastic energy density (EED) term

$$\varepsilon(\mathbf{r}) = \mu u_{ik}^2(\mathbf{r}) \quad (1)$$

which can be replaced by

$$\varepsilon(\mathbf{r}) = \mu [u_{ik}(\mathbf{r}) - u^{(0)}_{ik}(\mathbf{r})]^2 \quad (2)$$

$$u_n(\mathbf{r}) = (R/2g) \{ [(n+2)/(n-1) - ((n+3)/n) (r/R)^2] \times \nabla \Phi_n^{\text{eff}} + (2r/R^2) \Phi_n^{\text{eff}} \} \quad (3)$$

$$k_n = \{ 1 + (\mu \rho g R) / (2n^2 + 4n + 3/n) \}^{-1} \quad (4)$$

$$\Phi_n^{\text{eff}} = k_n \Phi_n + (1 - k_n) \Phi_n^{(0)} \quad (5)$$

where u_{ik} is the strain tensor, ($= \partial_k u_i + \partial_i u_k$); $u^{(0)}_{ik}$ is the 'reference' strain tensor which, for simplicity, we assume to be

derivable from a reference displacement $\mathbf{u}^{(0)}$ by $u^{(0)}_{ik} = \partial_k u_i^{(0)} + \partial_i u_k^{(0)}$. Again for simplicity, we assume that $\mathbf{u}^{(0)}$ represents the effect of an effective 'reference potential' $\Phi^{(0)}$ on the fluid body. That is, equation (2) is the elastic energy density for a self-gravitating body which froze when an external potential $\Phi^{(0)}(\mathbf{r})$ was acting on it, and is now distorted differently as a result of the replacement of $\Phi^{(0)}$ by the actual current potential Φ . Expanding all quantities in spherical harmonics, and denoting by subscript n any quantity belonging to the harmonic manifold of order n , the modified equations can be solved to obtain

$$u_n(\mathbf{r}) = R/2g \{ (n+2/n-1 - n+3/n (r/R)^2) \nabla \Phi_n^{\text{eff}} + 2r/R^2 \Phi_n^{\text{eff}} \} \quad (3)$$

where $n \geq 2$. The $n=0,1$ terms only determine the volume and centre of the initial sphere.

Where R and g are the radius and free fall surface acceleration, k_n is related to the n th order Love number⁸

$$k_n = [1 + (\mu \rho g R) (2n^2 + 4n + 3/n)]^{-1} \quad (4)$$

and

$$\Phi_n^{\text{eff}} = k_n \Phi_n + (1 - k_n) \Phi_n^{(0)} \quad (5)$$

For $\Phi_n^{(0)} = 0$, that is, for departures from spherical shape, equation (5) gives the well known results, whereas with $\Phi_n^{(0)}$ present, the body behaves as if fluid is under a potential which is a weighted average (with weight $k_n < 1$) of the reference and actual potentials.

For actual computation, it is easier to expand, in the usual way,

$$\Phi_n(\mathbf{r}) = gR(r/R)^n \sum_m \varepsilon_n^m y_n^m(\theta, \phi) \quad (6)$$

$$\Phi_n^{\text{eff}}(\mathbf{r}) = gR(r/R)^n \sum_m \eta_n^m y_n^m(\theta, \phi) \quad (7)$$

$$\Phi_n^{(0)}(\mathbf{r}) = gR(r/R)^n \sum_m \varepsilon_n^m(0) y_n^m(\theta, \phi) \quad (8)$$

and the surface radial displacement, which is the terrestrial topography, can be expanded to give

$$u_r(R, \theta, \phi) = R \sum_{n,m} u_n^m y_n^m(\theta, \phi) \quad (9)$$

Equation (5) is then transformed to give

$$\eta_n^m = k_n \varepsilon_n^m + (1 - k_n) \varepsilon_n^m(0) \quad (10)$$

and from equation (3):

$$\eta_n^m = - [2(n-1)/2n+1] u_n^m \quad (11)$$

Given η_n^m from the topography analyses and knowing ε_n^m from the actual external potentials, both $\varepsilon_n^m(0)$ and, therefore, the displacement $\mathbf{u} - \mathbf{u}(0)$, which causes the strain which determines the elastic energy density, can be calculated. Note that $\mathbf{v}_n = \mathbf{u}_n - \mathbf{u}_n(0)$ is, again, the displacement of an equivalent fluid body, acted upon by a potential $k_n(\Phi_n - \Phi_n^{(0)})$.

The variables controlling the irreversible release of elastogravitational energy are the $\varepsilon_n^m(0)$ values. In general, the total elastogravitational energy can be written, for $\varepsilon_n^m = 0$, as a sum of squares of the $\varepsilon_n^m(0)$; thus the various processes will act in such a way as to decrease the latter on the average. (Of course, over short time scales some of these could grow at the expense of others, as long as the total energy is decreasing.) The energy reduction process manifests itself in real body and surface motion, as shown by equation (9)–(11). Such a motion, which we shall tentatively consider as a form of continental drift, will depend strongly on the exact way in which the various $\varepsilon_n^m(0)$ values change. In order to try to understand this, we have assumed that the important physical processes are local, so that:

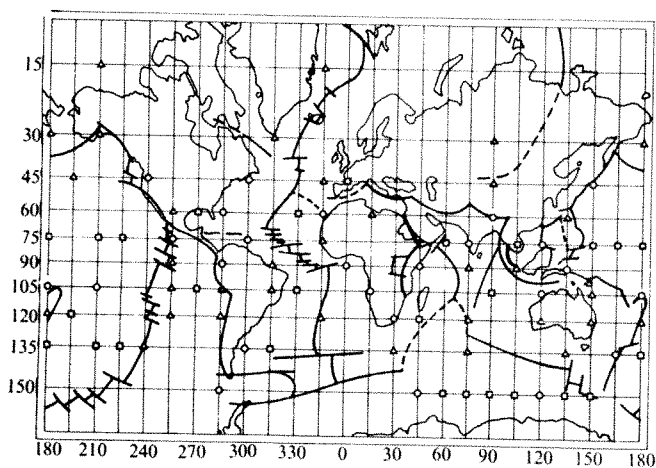

Fig. 1 The movement of the Earth's crust. The arrows represent du_r/dt as calculated from equation (13) in the special case that $\beta = 0$. A solid arrow indicates that du_r/dt is negative, corresponding to crustal sinking; a dotted arrow indicates that du_r/dt is positive, corresponding to crustal rising. Background map taken from Stacey, F. D., *Physics of the Earth*, (Wiley, New York, 1969.)

Fig. 2 A plot of EED maxima as calculated with the spherical harmonics coefficients of the Earth's topography in the presence of the Earth's rotational potential⁶. The figure is drawn for a spherical shell at 0.95 Earth radius. Triangles, latitudinal maxima (along a given latitude); boxes, longitudinal maxima (along a given longitude); circles, maxima in both directions. The background heavy lines represent known regions of seismic activity. Background map taken from Stacey, F. D., *Physics of the Earth* (Wiley, New York, 1969.)

$$d/dr[u_n(r) - u_n^{(0)}(r)] = -\alpha' [u_n(r) - u_n^{(0)}(r)] \exp[\beta \varepsilon(r)]$$

with suitable values of α' and β . This expression is equivalent to (with $\Phi_n = 0$):

$$d/dr u_n(r) = -\alpha u_n(r) \exp[\beta \varepsilon(r)] \quad (13)$$

The actual process of strain release described is considerably more complicated.)

We can apply our formulation to a simple model study—the behaviour of a self-gravitating sphere deformed by

$$\begin{aligned} u_r &= 0 & \text{for } \theta \geq \theta_0 \\ u_r &= -aR(1 - \cos(\theta - \theta_0)) & \text{for } \theta < \theta_0, \end{aligned} \quad (14)$$

where θ is the spherical latitude. This is a 'one-ocean' model of the Earth; θ_0 is the half angular width of the ocean; R the terrestrial radius; and a is a parameter specifying the depth of the ocean, chosen so that the centre of gravity of the deformed body is not too different from the undeformed body.

For this model, we have chosen θ_0 to be 60° , and examined both the EED distribution pattern and the displacement from the reference sphere (a sphere having the same mass and the same centre of gravity as that under consideration). We find that:

(1) the elastic energy is a maximum (of height 10 in arbitrary units) at the centre of the ocean, and falls smoothly to a minimum of 0.65 at 46° , rising again to a maximum of 3.2 at 64° , just off the coast; it falls smoothly again to a low of 0.06 at 118° and finally rises to a maximum of 1.16 at 180° .

(2) the radial component of the displacement vector from the reference sphere $u_r = \sum_{n \geq 2} u_{nr}$ is negative from 0° to 48° ,

positive from 50° to 112° , then negative again from 114° to 180° .

(3) the θ component of the displacement vector from the reference sphere, $u_\theta = \sum_{n \geq 2} u_{n\theta}$, is zero at both poles,

positive from 0 to 78° and negative from 80° to 180° .

We therefore infer that:

(1) it is reasonable to associate regions of maximal elastic energy density with seismically active regions. If our model ocean is regarded as a first approximation for the Pacific Ocean, then we predict seismically active regions in the centre of the ocean, (the Hawaiian Islands), the coasts, (Japan, South-east Asian coasts, the Indonesian islands, and the American Pacific coast) and opposite the ocean centre (the Middle East). These regions are, indeed, seismically active.

(2) Fault lines and plate boundaries can be induced inside the continental land mass as a result of the strain created by the ocean. If we assume, that $\tilde{u} \propto \Delta u$ on the basis of equation (13), we would expect fault lines at 50° and 114° , and a plate boundary at 80° . Moreover, the ocean tends to close in order to reduce the overall strain energy.

A second model study was devoted to the investigation of possible interference effects between two oceans, ocean A and ocean P, which are both described by expressions of the form of equation (14). Their maximum depths were chosen to have the ratio 4:7. Ocean A has a half-angular width of 25° and P has a half-width of 75° . The angle between the centres of A and P was chosen as 120° . We found that maxima in EED still exist on the coast and centre of P, and on the far side of the coast of A away from P. There is no EED maximum diametrically opposite to the centre of P because it is too close to the far side of the coast of A. This model shows that interference is quite important. Of course, this model is too rough to match the actual description of the Atlantic and Pacific Oceans.

In the first spherical harmonic analysis of the Earth's lithosphere and hydrosphere⁴, and to a certain extent, in subsequent analysis^{5,6}, the Mid-Atlantic Ridge was not prominently reproduced. As a result, we expect that our calculation of EED and displacements in the Atlantic region is less meaningful than the corresponding calculation for the Pacific Ocean. Using the various sets of spherical harmonic coefficients of the Earth's topography, we have calculated the EED distribution in various spherical shells in the Earth at distances of 1.0, 0.975, 0.95, 0.925, 0.9, 0.85, 0.8, 0.7, 0.6, 0.5, and 0.4 Earth radii for regions of 15° by 15° . We have carried out calculations both with and without the Earth's rotational potential. In each case, we have scanned for latitudinal maxima of the EED (along a given latitude) and longitudinal maxima of the EED (along a given longitude) for each spherical shell. We have associated regions of maximal EED with seismically active regions. Also, at a given angular coordinate, we searched for maxima in the function $r^2 \varepsilon(r)$ along the radius. We have associated such maxima with the 'focal points' of seismic regions. We have also calculated the displacement vectors

$$\mathbf{u} = \sum_{n \geq 2} \mathbf{u}_n \text{ and } \mathbf{u} - \mathbf{u}^{(0)} = \sum_{n \geq 2} (\mathbf{u}_n - \mathbf{u}_n^{(0)})$$

According to the simple model expressed by equation (13), the Earth's crust, at a point r , will move with a velocity proportional to the magnitude of \mathbf{u} , but oppositely directed to it. Figure 1 shows the plot of du/dr , calculated with the Prey coefficients⁴ with rotation included but without ocean waters as an external load and without isostasy, in the special case that β is 0. It clearly illustrates that oceans tend to close and that mountains tend to disperse.

Space does not permit presentation of all our EED results, which include calculations in each shell for each case considered. All shells in the region between 0.8 to 1.0 Earth radii have an EED pattern fairly close to the experimentally known distribution of seismically active regions, but not quite the same. In most cases, the shells at 0.95 and 0.925 Earth radii give best fits to observed seismic regions. Furthermore, inclusion of the Earth's rotational potential leads to closer agreement with observation. Figure 2 shows the EED maxima distribution in the 0.95 Earth radius shell, calculated with the most recent data⁶ in the presence of the rotational potential.

If only the latitudinal maxima are considered, there seems to be a better fit to the observed seismically active region. A way of understanding this is to suggest that the EED maxima, both longitudinal and latitudinal, are there. Latitudinal maxima are, however, sensitive to Coriolis forces, and so seismic activities may be more associated with latitudinal maxima than longitudinal maxima.

Along a seismic plate boundary, points on the same plate have EED maxima in the same spherical shell or in adjacent shells. In general, EED maxima for points on coastal plates lie closer to the Earth's surface than those on mid-oceanic plates.

A deformed body possesses elastic energy which is gradually released in irreversible processes. It may be possible to understand general features of seismic activity and continental drift as global phenomena related to irreversible strain releases. Although we have not reproduced EED maxima along the Mid-Atlantic Ridge, a ridge does tend to form in the middle of the Atlantic Ocean (Fig. 1). Our EED maxima distribution, in and around the Atlantic Ocean, could well correspond to a situation before the Mid-Atlantic Ridge was formed.

Refinements in the spherical harmonic analysis of the Earth's topography, and inclusion of the effects of isostasy and local variations in μ and g are desirable. Coupling to thermal convection is probably important, as thermal energy seems to be sufficient to move the continental plates³. Core-mantle coupling which would include the effects of the existence of the liquid core may also play an important role. The relaxation process described by equation (13) is obviously too simple and needs to be improved; this will require a better understanding of the solid-state physics of the Earth's crust. We hope to return to these and related questions elsewhere.

We thank Professor David Pines for his encouragement and for discussions. J. S. thanks the Physics Department of the University of Illinois. Professors G. J. Bruius and W. M. Kaula provided spherical harmonics coefficients. This work has been supported in part by the National Science Foundation.

Remote sensing and lake eutrophication

AN infrared photograph of part of Clear Lake, California (Fig. 1) shows beautiful, complex patterns of blue-green algal blooms which were not observed by conventional limnological techniques. Repeated observations of patterns such as these can be used to chart the surface movement of these buoyant algae and can also be used to help control algal scums in eutrophic lakes.

A considerable amount of microstructure is visible in the photograph, including plume and wave-like concentration. We use the term 'microstructure' because the distances between what are obviously very different concentrations of phytoplankton are only of the order of a few metres, which are small distances relative to the area of the lake (17,000 ha). Although sampling teams on the lake could see some evidence of surface algal concentrations, they did not observe the microstructure at all despite the

Fig. 1 Infrared aerial photograph of surface algal concentrations in the Upper Arm of Clear Lake, California, taken on May 11, 1973 with an International Imaging Systems Mark I multispectral camera with four 100 mm F. L. lenses and Kodak Type 2424 film. The image is 5 km across. a, Wake of boat. Images were simultaneously recorded in red (590-690 nm), green (470-590 nm) and blue (400-470 nm) light. The infrared light used to record this image (730-950 nm) should not be confused with emitted thermal radiation (5,000-14,000 nm). Solar elevation above the horizon was 35°. On the water, dip samples from the first 10 cm of the water column were measured for turbidity and analysed spectrophotometrically for soluble phycocyanin-c and particulate chlorophyll *a* after methanol extraction³. Secchi disc depths and field notes were recorded at each station. One of us (A.J.H.) devised an aerial photographic technique for surface blooms, which is more available to the average limnologist. A conventional hand-held SLR camera with a through-the-lens light meter, 35-mm lens, standard colour film and a rotatable polarising filter gave a fair impression of the bloom microstructure from a small highwing airplane at an altitude of 2,000 m. Polarised light brought out algal surface patterns but in less detail than the multispectral pictures.

fact that the boat tracks are visible in Fig. 1. Measurements from the boat showed that the lake is virtually free of suspended sediment and that it supports a near monoculture of *Aphanizomenon flos-aquae*¹. Lake surface turbidity, including algae, was only 3 Jackson Turbidity Units. Concentrations of chlorophyll *a* were measured as 14 and 255 $\mu\text{g l}^{-1}$ in two of the photographed areas and we are therefore sure that the pattern resulted from a single species of blue-green algae. Complex patterns such as these cannot be determined using conventional techniques because major changes in algal distribution can occur in a few minutes and the details are invisible from a moving boat. Sky reflections, internal reflections of upwelling light and the disturbance from the boat itself all add to the problem.

Buoyant, gas-vacuolate blue-green algal blooms are a considerable nuisance in Clear Lake. For example, when the Upper Arm of Clear Lake was photographed (Fig. 1), the surface patterns were very different from those in the Oaks Arm. Algae formed dense streaks several metres wide and 10 cm deep and had chlorophyll *a* concentrations of approximately $10^3 \mu\text{g l}^{-1}$ relative to adjacent values of approximately $10^2 \mu\text{g l}^{-1}$. Physical concentrations such as these, if prolonged, would be catastrophic for both algae, which would die, and humans, who would suffer from the smell. Blue phycocyanin-c, a paint-like pigment virtually unique to blue-green algae, is lost from their cells upon death. Even by 09.00 LT the streaks contained up to 500 times more free phycocyanin-c than was observed in nearby areas, indicating considerable decay of the surface phytoplankton. In spring *Aphanizomenon* can fix atmospheric

nitrogen gas into cellular material and is responsible for up to 50% of the lake's annual intake of nitrogen¹⁻⁴ and therefore, by definition, for much of its eutrophic state. Observations of the destruction of *Aphanizomenon* are important in the control of the extreme eutrophic state of the lake.

Although we believe that most of the observed patterns resulted from *Aphanizomenon* (we also observed a few which resulted from suspended sediment), spectral signatures of the algal patterns varied. On May 11, 1973 algal concentrations were bright in infrared light (Fig. 1); a photograph of the same area in red light provided a similar, but less contrasting, response and photographs in blue and green light showed no patterns. A different spectral signature occurred on June 21, 1973: algal concentrations which were still bright in infrared light, appeared as similar, though darker patterns in blue, green and red light. The spectral signature observed on May 11, however, only occurred in limited areas. Importantly, lysed (dead) algal streaks were bright in all spectral regions. Temporal and spatial signature variations such as these result from any combination of several factors: algal distribution and concentration in the water column⁵, gas vacuolation in the algae⁶, or background turbidities or anomalous concentration effects⁷.

We thank C. J. W. Carmiggelt, M. Funk and W. Wurtzbaugh for help with lake measurements, and V. R. Oberbeck and W. L. Quaide for discussion. This work is part of a joint programme between NASA, the University of California at Berkeley, and the Clear Lake Algal Research Unit; the latter is supported by the California Department of Water Resources and the County of Lake, California.

X-ray photoemission spectroscopy

We wish to report the first X-ray photoemission spectroscopy (XPS) experiments performed at Stanford Synchrotron Radiation Project, using synchrotron radiation from the Stanford Positron Electron Accelerator Ring (SPEAR) facility. The photoemission technique has been used extensively in the study of the electron properties of materials^{1,2}.

The main emphasis was on the study of the feasibility of using the favourable properties of synchrotron radiation to achieve high resolution XPS. A resolution of 0.6-1.0 eV (or 0.9-1.5 eV) is achieved in commercially available XPS machines with (or without) monochromatised radiation. We have obtained a total experimental width of 0.42 eV, implying a resolution of about 0.25 eV. Studies in the X-ray region have been limited to the few photon energies determined by characteristic X-ray emission lines (mainly Al $K\alpha_{1,2}$ and Mg $K\alpha_{1,2}$ radiation at 1486.7 eV and 1253.6 eV, respectively, the intensities of which are high enough and the characteristic linewidths of which are small enough to be useful as a monoenergetic X-ray source³. Synchrotron radiation⁴ provides a continuous wavelength spectrum, which for the SPEAR storage ring with a critical wavelength⁴ of $\lambda_c = 4.6 \text{ \AA}$ (at a beam energy of 2.5 GeV) extends down to a fraction of an angstrom ($\approx 1/10 \times \lambda_c$) with considerable intensity. The advantages of using synchrotron radiation for XPS experiments have been reviewed⁵, and parameters of the SPEAR storage ring have been summarised.

In a photoemission experiment the sample is irradiated with monochromatic radiation and a kinetic energy analysis is performed on the photoemitted electrons. Our experimental apparatus, consisting of a beam extractor, a crystal monochromator and an electron spectrometer (Fig. 1). The beam extractor is a 10 m long ultrahigh vacuum pipe ($\Phi = 8$ inches) which is used to channel the synchrotron light from the storage ring out to the experimental area. The beam extractor contains, among other things, instrumentation for collimating the synchrotron beam in both the horizontal and vertical planes. The X rays are allowed to pass two Be foil filters to reduce long wavelength radiation, and through a Be window (250 μm thick), which provides a vacuum tight connection between the ring (10^{-9} torr) and the monochromator (atmospheric He). The crystal monochromator uses two flat Si (220) crystals in the parallel mode and a Si (440) channel-cut crystal in the anti-parallel mode. A third crystal is optional and was not used for these experiments. The first crystal deflects the X-ray beam downwards in the vertical plane and the beam emerges from the second crystal horizontally about 20 cm below the centre-line of the original beam. The monochromator is positioned inside the radiation shielding of the storage ring and must be remotely controlled. The monochromatic X-ray beam (8,000 eV) passes through a hole in the radiation shielding and into the electron spectrometer through a thin (50 μm) Be window, about 15 m from the source. The electron spectrometer consists of an ultra high vacuum (UHV) chamber (base pressure 4×10^{-11} torr) housing an energy analyser, a sample flange, and accessories for the preparation of UHV samples. The energy analyser is a double-pass cylindrical mirror analyser with a channeltron as the electron detector. Standard techniques for fast pulse counting were used for the data acquisition.

Fig. 2 Electron distribution curve for the 4f doublet of gold. The Fermi level is chosen as the reference level for the binding energy. a, $4f_{5/2}$ peak; b, $4f_{7/2}$ peak; c, 0.42 eV (FWHM).

The performance of our XPS machine was tested by measurements of photoemitted electrons from inner core levels in the noble metals Cu, Ag and Au. The measurements were taken on thin films evaporated *in situ* in the UHV chamber. The observed distribution curve for the well known and extensively examined 4f doublet in Au is shown in Fig. 2. The total accumulated number of counts is plotted against the binding energy of the electrons, using the Fermi energy as the reference level. The counting rate is normalised to an *e*-beam current of 20 mA in SPEAR. During these measurements the ring was run at a beam voltage of 2.5 GeV and an *e*-beam current of 20–40 mA (the beam current typically decays from 30 to 20 mA in 3–4 h, after which the beam is dumped and the ring refilled). The horizontal scale has been calibrated so as to give the binding energy for the $4f_{7/2}$ level, which was reported by Ley *et al.*⁷. The most remarkable thing about the spectrum (Fig. 2) is the extremely narrow width of the lines, demonstrating the high resolution capability of the XPS machine. A linewidth of 0.42 eV at full width at half maximum (FWHM) is obtained from Fig. 2, which is about a factor of two better than results from X-ray tube sources without a monochromatised Al $K\alpha_{1,2}$ source⁸. The splitting between the two peaks, and their relative heights (Fig. 2a, b), are in excellent agreement with earlier results³. Signal-background and signal-noise ratios are expected to be improved after a minor modification of the experimental set up. Three factors contribute to the observed linewidth of 0.42 eV at FWHM: the inherent width of the 4f photoline; the resolution of the energy analyser; and the resolution of the crystal monochromator (including the effects of slits and collimators). The energy resolution of the doublepass cylindrical mirror analyser is well known, and is 0.6% of the pass energy for the electrons. We chose a pass energy of 20 V, thus, the contribution to the resolution from the energy analyser is 0.12 eV. It is more

difficult to give an exact figure for the contribution from the crystal monochromator, because of the complexity of the slits and collimators, and because of the difficulty of estimating the source size. A consideration of all of the geometrical factors, however, suggests that it should lie somewhere between 0.25 eV and 0.35 eV. With the arbitrary assumption of Gaussian line shapes the inherent linewidth would then be 0.2–0.3 eV. It can be assumed, however, that the line shapes are neither pure Gaussian nor Lorentzian. All that we can therefore conclude at present is that the intrinsic linewidth is certainly less than 0.3 eV but probably 0.10–0.15 eV. We are not aware of any theoretical estimate of the different physical processes (for example, radiative and non-radiative Auger transitions) contributing to the linewidth. Published calculations of Auger transition rates do not extend out to the 4f shell⁹.

The calculated photon flux after the monochromator, using the SPEAR parameters already given, is 10^9 – 10^{10} photons $s^{-1} cm^{-2}$ which is consistent with our flux measurement using an ionisation chamber. The useful flux on the sample is determined by the effective aperture of the energy analyser. Finally, we should comment on the counting rate which under the present running conditions of the storage ring and the electron spectrometer is 25 counts s^{-1} on the 4f peaks (Fig. 2). Obviously, this counting rate excludes the possibility of conveniently studying valence bands and core lines with considerably weaker intensity than the Au 4f levels. The intensity of 8,000 eV X rays will, however, increase about 50 times, after the upgrading of the SPEAR storage ring (planned for summer 1974), and thus the required data acquisition time will be considerably shortened.

We acknowledge the help and discussions of Drs N. Alexandropoulos, G. Brogren, R. Deslattes, P. Eisenberger, E. Hoyt, B. Kincaid, E. Meieran and H. Winick. The support of SLAC Director W. K. H. Panofsky and SPEAR Director B. Richter and the cooperation of SLAC staff, in particular G. E. Fischer, N. Dean and J. Harris, was invaluable throughout. This work was supported by the National Science Foundation, in cooperation with the US Atomic Energy Commission.

Electrically driven instability in elastic liquids

We report here a striking phenomenon which we have observed in some elastic liquids. The phenomenon was discovered during the cleaning out of a glass vessel which contained a newly prepared solution of a polyisobutene of high molecular mass in a polyisobutene with a low molecular mass. The liquid was rather viscous, and so a good proportion of it remained on the walls of the

Fig. 1 The formation of fine jets of liquid after a polyisobutene solution has been torn away from a glass surface. The glass rod in the photograph has a diameter of 6 mm.

container. We decided to recover this by utilising the elastic properties of the solution and 'winding' it onto a glass rod. Using this method the liquid can be torn completely free from the walls of the container. Having thus removed some of the liquid from the container we found that the liquid on the rod spontaneously developed a number of fine streamers (Fig. 1). These emanated from irregularities on the surface of the liquid and their tips moved away from the rod at speeds of several cm s^{-1} .

Using an electroscope we established that the process of tearing the liquid from the walls of the container resulted in a separation of electrical charge. We also noticed that the streamers were readily attracted to nearby objects.

It has been known for many years¹ that the horizontal free surface of a liquid in a vertical electric field can be unstable, resulting in the formation of vertical jets of liquid if the field intensity is sufficiently large. We believe that the present phenomenon is an example of this instability. As the winding-on procedure produces irregularities in the free surface, the charge that is generated in the process of tearing the liquid from the container will not be uniformly distributed over the surface, thus giving rise to local field intensities near these irregularities much larger than the average. Presumably these 'local' fields can exceed the critical field intensity required for the described instability to occur, and a jet (or streamer) of liquid forms in exactly the same way as that described by Taylor¹. We have found that these streamers grow to great lengths (to many thousands of diameters) without breaking and can be so fine as to be quite difficult to see with the naked eye. This remarkable cohesion is most probably aided by the very good spinnability of many elastic liquids², which allows them to be drawn into extremely fine threads without breaking. (Taylor found in his experiments¹ that, if he used a conducting liquid, a steady uniform jet of liquid was formed when the field was sufficiently strong. If, however, the liquid was a poor conductor, such as transformer oil, the jet did not properly establish itself and took the form of a series of droplets. We repeated Taylor's experiment using the polyisobutene solution, which has an extremely low conductivity, and found that the instability resulted

in the formation of a steady uniform jet. We attribute this to the good spinnability of the non-Newtonian polyisobutene solution, as opposed to the Newtonian behaviour of transformer oil.)

We tried to reconstruct our observation by spreading a small quantity of the liquid (taken from the stock solution) on a glass plate and then 'tearing' the liquid from the plate by winding it on to a rod. The phenomenon was not observed immediately, but after the liquid had been left on the plate for a day in the open air, we found that the phenomenon could once more be produced easily. Further investigation indicated that the composition of the plate (whether glass, perspex, or a metal) did not affect the experiment noticeably, but that it would not work when the rod was a conductor.

At this stage we decided that the charge separation might occur in a similar manner to that in which charge arises when petrochemical mixtures flow through pipelines. In such cases it has been found that the formation of the charge depends on the presence of trace polar impurities³. In order to test this idea we placed some fresh liquid on a glass plate, put the plate in a desiccator for a week, and tried to observe the phenomenon. No streamers were found but after the liquid on the plate had been left exposed to the air for a few hours we were again able to produce the instability. It seems, therefore, that in our experiments a small amount of water from the air was necessary for the charge generation.

We believe that the extremely low electrical conductivity of polyisobutene solutions is an important feature of the experiment, as it is essential that the field is maintained while the streamers are forming, and this requires that the charge should not leak away too quickly. The phenomenon has also been observed with a solution of polystyrene in di-phthalate.

Bordoni peak formation as a result of a martensitic transformation

THE indium-thallium alloys in the composition range 16–31 atom% Tl undergo a martensitic phase transformation from the higher temperature f.c.c. form to the lower temperature f.c.t. modification^{1,2}—a transformation which is well suited to ultrasonic studies. Here we report ultrasonic attenuation measurements, which have revealed the development of an internal friction peak which results from the passage of 27 atom% Tl alloy single crystals through the phase transition (which occurs at 127 ± 2 K for this composition³). The general behaviour of this peak strongly suggests a relaxation type of effect similar to that first observed by Bordoni in copper⁴. Such peaks are either absent or negligibly small in well annealed metals; but they are produced by plastic deformation and are considered to arise from thermally activated processes involving dislocations⁵. We can therefore expect that any dislocations which are formed as a result of the martensitic transition would give rise to such a peak, and that it could be detected

ultrasonically, provided that the investigated ranges of ultrasound frequency and temperature are appropriate to the activation energy involved.

Measurements were made on [110] oriented, single crystal samples of the alloy, of composition 27 atom% Tl, cut from a boule of about 4 cm³ which had grown in a horizontal zone furnace. Ultrasonic pulse-echo measurements were made at 14 MHz and 42 MHz with longitudinal waves and [100] polarised shear waves, respectively (Fig. 1). A large absorption peak occurs at the transition temperature T_c (refs 3 and 6). The peak temperature is independent of frequency, although it does differ somewhat between warming and cooling, as would be expected for this transition. The additional feature of the attenuation behaviour (shown in more detail in Fig. 2) is the peak which occurs at temperatures higher than T_c and which moved to higher temperatures when the driving frequency was raised. During each experiment the sample was taken through a cycle of cooling from room temperature to below T_c (thus producing a banded twin f.c.t. structure) and then warming back to 300 K to reverse the process and to re-establish the single crystal form; the temperature change was continuous, except at the end points. For the first few (≈ 5) cycles following the original spark cutting and planing of the crystal, the additional attenuation peak could be seen only during the warming part of the cycle and was not seen during cooling (Fig. 1). After a further few cycles, however, the peak became established during both warming and cooling (Fig. 1). Subsequent measurements over a long period of time showed that the peak height decreased gradually, until after about eight months it had vanished almost completely.

Fig. 1 The temperature dependence of the attenuation of ultrasonic waves propagated along the [110] direction in an In-27 atom% Tl alloy. *a*, 14 MHz curves (longitudinal waves); *b*, 42 MHz curves (shear waves, polarised [001]); ●, cooling; ×, warming; ○, initial cooling. The peaks at 127 K (on cooling) result from the phase transition, and the Bordoni peak appears at about 250 K.

Fig. 2 Collected data of the Bordoni peaks found for ultrasonic waves propagated in the [110] direction in In-27 atom% Tl crystals. *a*, 70 MHz curve, shear wave (sample A); *b*, 42 MHz curve, shear wave (sample A); *c*, 42 MHz curve, longitudinal wave (sample B); *d*, 42 MHz curve, longitudinal wave (sample A); *e*, 14 MHz curve, longitudinal wave (sample B); *f*, 14 MHz curve, shear wave (sample A). These data were obtained during the period when the peaks could be seen on both warming and cooling, and before their amplitude had become too small to measure.

In general, the observed effects are characteristic of Bordoni peaks in f.c.c. metals. For example, Bordoni⁴ first found that the internal friction peak in copper was reduced by about 30% after annealing at 150° C for 10 h. Room temperature annealing of the Bordoni peak, of the kind observed here, is well known in aluminium^{7,8}. In indium-thallium alloys the peak temperature does not depend appreciably upon the number of passes through the transition. This corresponds with the usual finding: that the Bordoni peak position is not very sensitive to prestrain, annealing or impurities. The results in Fig. 2 can be used to test a relaxation process hypothesis. An activation energy, E , is defined, and the peak temperature T_m , and driving frequency, ν , can be related by an Arrhenius type of expression

$$\nu = \nu_0 \exp(-E/kT_m) \quad (1)$$

in which ν_0 is an attempt frequency. A straight line on an Arrhenius plot (Fig. 3) gives a reasonable fit to the present results. Several determinations were made of T_m at each frequency with different ultrasound wave polarisations, on two different [110] samples cut from the same boule, and the

Fig. 3 Arrhenius plot to determine the activation energy and attempt frequency corresponding to the Bordoni peak, induced by passing through the transition. ●, Sample A; +, sample B; L, longitudinal waves; S, shear waves.

variations were found to be small. The activation energy, E , was found to be 0.24 ± 0.05 eV and the attempt frequency, ν_0 , $1.5 \pm 0.4 \times 10^{13}$ Hz. Applied to Bordoni peaks in f.c.c. metals in general this procedure gives activation energies of the order of 0.1 eV: for copper, E is 0.1–0.15 eV (with $\nu_0 = 10^{10}$ – 10^{13} Hz); for aluminium, E is 0.25 eV ($\nu_0 = 10^{14}$ Hz) (ref. 5). The peak parameters obtained for indium-thallium alloy studied here, fall into the same range. It is interesting that there is no significant difference, within the limits of experimental error, between the activation energies obtained for the longitudinal and the transverse modes. A difference can occur, however, when the resolved stress component differs on the slip plane corresponding to the polarisations of the longitudinal and transverse ultrasonic waves⁹.

The general features of the peak in the ultrasound attenuation in the alloy are consistent with those of Bordoni peaks. In other materials such peaks have been shown previously to result from dislocation motion, and to occur at high dislocation densities. The peaks in the 27atom% Ti alloy were formed after passage of the crystals through the martensitic transition, and back. If a dislocation damping mechanism is assumed, then not only is the frequency dependence of the peak temperature accounted for, but so is the observation that the peak appears initially only on warming. The strains involved during the transformation must produce a large number of dislocations which then interact with the ultrasound waves as the sample is warmed up, and anneal out when it is held at room temperature for several hours (300 K is approximately 0.7 of the melting temperature). Therefore, subsequent cooling does not result in the reappearance of the peak. But if after several cycles, the dislocations become pinned sufficiently for short period annealing to become ineffective in causing their removal, then the peak will appear in both the cooling and the warming parts of the cycle, as is observed. The attenuation peak results provide experimental evidence of the production of dislocations during the martensitic transformation.

Determination of the gas constant by an acoustical method

A NEW value for the gas constant, R_0 , has been obtained from measurements of the velocity of sound, c , in argon at the temperature of the triple point of water. Velocity measurements were made using a low frequency variable-path acoustic interferometer, operating at a frequency of 5.6 kHz (ref. 1). Ninety eight independent measurements of sound velocity were made over a range of pressures from 0.3–2.0 atm. A quadratic least squares fit was made of c^2 against pressure, and the resulting acoustic isotherm was extrapolated to zero pressure to yield a value for c_0^2 , the velocity in the limit of low pressures. The gas constant was then obtained from the relationship

$$c_0^2 = \gamma R_0 T / M$$

where $\gamma = 5/3$, $T = 273.16$ K, $M = 39.9478$ g mol⁻¹ and c_0^2 was the experimentally determined value of $94,768.9 \pm 2.1$ m² s⁻². The uncertainty quoted for c_0^2 is the standard error on the intercept of the acoustic isotherm.

The value for the gas constant thus obtained is

$$R_0 = 8,315.59 \pm 0.18 \text{ J K}^{-1} \text{ kmol}^{-1}$$

The uncertainty quoted here is the standard error in the result, which stems from the standard error in c_0^2 arising from random errors in the measurements of sound velocity. It is equivalent to a standard error of 22 parts per million (p.p.m.) in R_0 .

The largest systematic uncertainty is that arising from the uncertainty in the isotopic composition of the argon used in the measurements, and is thought not to exceed 7 p.p.m. Errors in temperature measurement, acoustic frequency and the measurement of displacement in the interferometer are considered negligible, and errors resulting from chemical impurities in the argon are not thought to lead to a systematic uncertainty greater than 3 p.p.m. The major uncertainty in the result is thus that arising from random errors in the measurement of velocity.

Full details of the experimental method and results will be published.

This new value for R_0 is greater by $1.18 \text{ J K}^{-1} \text{ kmol}^{-1}$ (142 p.p.m.) than that based upon measurements of the density of oxygen and quoted as $8,314.41 \pm 0.26 \text{ J K}^{-1} \text{ kmol}^{-1}$ (ref. 2).

Solution evaporation method for solid state ESCA studies

ALTHOUGH considerable effort in electron spectroscopy for chemical analysis (ESCA) has been channelled into the development of narrow line sources¹⁻⁴, there has been little attention to the problem of increasing ESCA resolution by decreasing the large linewidth contribution from involatile non-conducting solid samples. For such samples, most workers have spread a thin layer of solid on to sticky tape^{5,6}, or have used a metal mesh as host matrix⁷⁻⁹. Al has also been suggested as a sample backing by P. E. Larsen. These procedures generally provide widths approximately 1 eV broader than those from the gas phase¹, thin condensed phase¹⁰, or from conductor¹ spectra. The procedures normally involve the use of a few mg of compound, even though ESCA should be sensitive to $\sim 10^{-8}$ g of a material^{2,11}.

We describe here a simple technique for evaporating very dilute solutions of compounds on to acid-etched Al plates which, first, usually appreciably decreases the linewidths of non-conducting samples; second, enables good spectra to be obtained using μg amounts of compound; and third, minimises charging effects and calibration problems.

All spectra were recorded using an ESCA-36 McPherson Instrument and Mg K α radiation. To avoid decomposition of samples, low X-ray power (15 mA \times 8 kV) was used for as short a period as possible. Spectra were calibrated using the Au evaporation technique^{12,13}, and an argon ion gun (10 keV argon ions) was used to etch a Sn metal foil *in situ* in order to obtain a spectrum of pure Sn metal. Besides the energy levels of direct interest in this study

Fig. 2 Normalised intensity of the Pb 4f_{7/2} line against amount of Pb(NO₃)₂ (μg) on the Al plate.

(Pb 4f, and Sn 3d), spectra of energy levels of other elements (such as C 1s, N 1s and O 1s) in the compounds were always recorded.

Alcan AA 3003 aluminium plates (2 cm \times 1 cm \times 0.06 cm) were lightly etched for 2-3 min in 3 M HCl until they were readily wettable with H₂O. Purer Al (Fischer 99.9% purity) was also tried with similar results. More extensive etching or roughening with fine emery paper invariably leads to the poorer results. Pt foil further reduced charging effects but did not wet as well. The etched Al plates were washed with H₂O and acetone and dried in an oven at 70° C.

Generally, solutions of between 10^{-2} M and 10^{-4} M of a given compound were prepared and 3-20 μl pipetted on to the Al plate. Volatile solvents such as benzene readily spread over the plate. Because of the high surface tension of H₂O, the end of the micropipette was used to spread aqueous solutions over the plate; if the plate was sufficiently etched, the water would wet the entire plate. The solvent was then allowed to evaporate in air.

The use of such small amounts of samples is an aid to minimising vacuum problems encountered with slightly volatile or unstable compounds.

An adequate spectrum of 0.4 μg of Pb(NO₃)₂ on a 2 cm² plate can be obtained in 75 min, using low X-ray power, and the linewidths (1.60 eV) are narrower than those (1.70 eV) for the 6 mg of Pb(NO₃)₂ solid (Fig. 1c). It is interesting to compare our results with those obtained by Hercules *et al.*¹¹ using complexing surface groups. We obtained the spectrum on 0.4 μg of compound, whereas they used 2,400 scans (for an unspecified length of time) to obtain a spectrum on ~ 2 μg of Pb.

Considering the area of the Al plates (2.0 cm²), assuming that the area taken up on the surface by a Pb(NO₃)₂ molecule is ≈ 20 Å² and that there is an even distribution of Pb(NO₃)₂ molecules on the surface, 1 μg of Pb(NO₃)₂ corresponds to 1.8 monolayers. Thus, the spectrum in Fig. 1c corresponds to that for about one monolayer of Pb(NO₃)₂. This suggests that considerably smaller amounts of Pb(NO₃)₂ could be detected at higher X-ray powers and longer scan times.

Furthermore, the reproducibility of the results (Fig. 2) is surprisingly good considering the potential difficulties in obtaining an even distribution of molecules on a surface. It is also interesting that the intensity begins to level off after a few μg of compound, although we have found that the normalised intensity continues to increase slowly with increasing amounts of Pb(NO₃)₂ on the plate. The reproducibility, combined with the narrower linewidths and the levelling off of the intensities, strongly indicates a reasonably even distribution of molecules on the surface.

Fig. 1 Pb 4f spectra of Pb(NO₃)₂ taken using a Mg anode and an X-ray power of 120 W. The binding energies are uncorrected for charging effects. See Table 1 for corrected values. The lines drawn through the spectra are seven point smooths. a, 6.1 mg of solid Pb(NO₃)₂ spread evenly onto an acid etched Al plate; time of accumulation = 15 min. b, 3.8 μg of Pb(NO₃)₂ from 10 μl of a 1.6×10^{-3} M Pb(NO₃)₂ solution in H₂O; time of accumulation = 75 min. c, 0.4 μg of Pb(NO₃)₂ from 10 μl of a 1.16×10^{-4} M Pb(NO₃)₂ solution in H₂O; time of accumulation = 75 min.

		142.4	141.9		138.9
				84.2	

* Au 4f_{7/2} = 84.0 eV.

Figure 2 indicates that with further improvement of the technique, there could be two very important uses both in ESCA and Auger spectroscopy: calibration curves for quantitative analysis, and escape depth studies.

The results (Fig. 1 and Table 1) also indicate that charging effects are minimised in the solution evaporated samples, relative to the solid spectrum, although the corrected binding energies are the same within the error for all samples. Pb(NO₃)₂ from solution evaporation is still about 0.5 eV compared to 139.6 eV for a solution evaporated sample, whereas the corrected Pb 4f_{7/2} peak is at 138.9 eV and 138.8 eV, respectively. The Au calibrations show that the Pb (NO₃)₂ from solution evaporation is still about 0.5 eV charged relative to Au on the Al plate. Thus, the Au 4f_{7/2} line (84.0 eV for Au metal) is at 84.2 eV on the etched Al plate, but is at 84.6 ± 0.2 on the Al plates with evaporated Pb(NO₃)₂. Au linewidths of 1.40 ± 0.05 eV were obtained for all Au evaporations.

It is apparent that the solution evaporation technique is ideally suited to internal calibration as used in other forms of spectroscopy, and in ESCA spectra of volatile solids in which a compound such as perfluorocyclohexane

(C₆F₁₂) is cocondensed with the compound of interest¹⁴.

For many molecular Sn(IV) compounds, the solution evaporation method leads to significant decreases in linewidths relative to spectra taken in the conventional manner, especially when large charging shifts are present. The minimum Sn 3d linewidths for a conductor (Sn metal) obtainable on our equipment are 1.05 ± 0.05 eV (Fig. 3a) whereas that for a molecular non-conductor (Ph₄Sn) is 1.20 ± 0.05 eV. In contrast, typical 3d linewidths on Ph₄Sn solid are 1.50 ± 0.05 eV. Sn 3d linewidths for a number of other Sn compounds are 1.30 ± 0.05 eV, but others such as Me₂Sn (acac)₂ (acac = anion of acetylacetone) give markedly larger linewidths of 1.65 ± 0.05 eV. Solid samples have larger linewidths probably because of differential charging⁹. For some molecular Sn compounds, narrow linewidths can also be obtained by using very thin solids spread on to the etched Al plates.

We are grateful to the National Research Council of Canada for generous financial support.

BIOLOGICAL SCIENCES

Actinomycin D and RNA transport

ACTINOMYCIN D, a potent inhibitor of RNA chain propagation of DNA-directed RNA transcription¹⁻³, has been widely used for studies of turnover and transport of RNA in a variety of cell systems, to try to demonstrate that nuclear RNA labelled before the addition of actinomycin D is transported to the cytoplasm. It has been found that most labelled RNA remains in the nucleus⁴⁻⁸. It has been shown that the decrease in radioactivity of the heterogeneous nuclear RNA in HeLa cells is not accompanied by transfer of appreciable material to the cytoplasm⁹. Results of such experiments have even indicated that no transfer of rapidly labelled RNA from nucleus to cytoplasm occurs⁵. Recent studies on the effect of actinomycin D have raised doubts as to the validity of conclusions based on experiments including it. A prolonged half-life of mRNA due to actinomycin D has been observed in liver cells¹⁰, and the decay time of mRNA in HeLa cells has been found to be considerably shortened by treatment with this antibiotic¹¹. A non-physiological breakdown of rapidly labelled RNA by actinomycin D in primary chick fibroblasts has also been reported¹².

In studies of RNA transfer from nucleus to cytoplasm by chase experiments with actinomycin D, the length of the labelling period before inhibition is very important. Actinomycin D, being a template inhibitor, binds to DNA, and thereby efficiently blocks elongation of nascent RNA molecules. The use of too short pulse labelling before administration of the drug may imply that, at the onset of inhibition, most of the radioactivity is confined to nascent RNA chains that cannot be released from the chromosomal sites during the ensuing chase with actinomycin D. Here I describe experiments supporting this idea. Transport of labelled chromosomal high molecular weight RNA to the cytoplasm after actinomycin D chase can be demonstrated if the period of prelabelling is sufficiently long (more than 25 min), and if labelled RNA has appeared in the nuclear sap before the addition of inhibitor.

Salivary glands were isolated from fourth instar larvae of the dipteran *Chironomus tentans*¹³. Four animals were used in each experiment. Four salivary glands were explanted into 50 μ l of modified Cannons medium¹⁴⁻¹⁵ supplied with tritiated cytidine and tritiated uridine (Amersham) at specific activities of 25–30 Ci mmol⁻¹. After prelabelling for 25 or 45 min, actinomycin D (Calbiochem, Los Angeles) was added. The sister glands were used as control glands and the incubations were carried out at 18° C. Fixation, microdissection, extraction of RNA and electrophoresis in 1% agarose were performed as described elsewhere¹⁶⁻¹⁸. After the electrophoretic run, the gel slabs were treated with cold TCA to aid the removal of non-specific label¹⁹. The analyses of nuclear and cytoplasmic RNA from glands incubated with actinomycin D showed that labelling was inhibited by more than 98% (ref. 16). After 90 min of normal labelling with tritiated nucleosides, the chromosomal RNA acquired nearly maximal labelling, and a large amount of label appeared in the cytoplasm. A total length (pulse + chase) of 90 min was therefore considered as a suitable period for incubation.

The electrophoretic analyses of chromosomal RNA (Fig. 1a), nuclear sap RNA (Fig. 1b) and cytoplasmic RNA (Fig. 1c) after 25 min of labelling and after 25 min of labelling plus 65 min of synthesis inhibition with actinomycin D are presented in Fig. 1. The profile of chromosomal RNA after 25 min of incorporation displays the usual bimodal distribution

Fig. 1 Electrophoretic separations of, *a*, chromosomal RNA, *b*, nuclear sap RNA and, *c*, cytoplasmic RNA after 25 min of labelling and after 25 min labelling + 65 min of synthesis inhibition. Four glands from four different animals were placed in an incubation droplet of 50 μ l containing 100 μ Ci tritiated cytidine and 100 μ Ci tritiated uridine, and their sister glands were placed as controls in another 50 μ l of the same medium. The glands were incubated at 18° C for 25 min. Next, actinomycin D was introduced to one of the droplets at a concentration of 10 μ g ml⁻¹ and the glands were incubated for another 65 min, while the incubation of the control glands was stopped. After incubation the glands were fixed, and the cell components from five cells per gland were isolated by micro-dissection. The labelled RNA from each sample was released by pronase-sodium dodecyl sulphate treatment, and the electrophoresis was carried out in 1% agarose gel. To remove actinomycin D and RNase-resistant radioactivity the gels were treated with cold TCA¹⁹. At the end of the run the whole gel slab was placed in a 250 ml beaker containing 5% TCA at 4° C, and washed for 60 min. The treatment was repeated in a new volume of TCA and the gel was finally washed twice for 40 min in 1 l of distilled water at 4° C. Before radioactivity measurement, the gel was sliced and the slices were transferred to Packard counting vials, each containing 10 ml of toluene scintillator (1 l of which contains 30 ml solouene (Packard), 5.5 g of Permablend (Packard) and 20 ml methoxyethanol), incubated for 3 h at 60° C and finally counted in a Packard liquid scintillation spectrometer (Model 3380). *E. coli* RNA was used as marker (23S, 16S and 4S). The position of 75S and 30S were determined in parallel analyses of BR 2 RNA nucleolar RNA respectively. ●, Normal cells; ○, cells treated with actinomycin D.

with a peak in the 4S range and with label heterogeneously distributed in the 16–100S range. The subsequent treatment with actinomycin D for 65 min reduced the labelling of chromosomal RNA to 50–60% of the control values rather uniformly in the whole spectrum. The electrophoretic pattern of 25 min-labelled nuclear sap and cytoplasmic RNA shows only trace amounts of label in the high molecular weight ranges, but there is a rather distinct peak in the 4S region. During the ensuing 65 min of actinomycin D chase, no significant quantity of labelled heterogeneous RNA was released from the chromosomes into the nuclear sap. It is, of course, not possible to exclude that a release of heterogeneous RNA to nuclear sap may take place, but the product must be degraded instantaneously after its detachment. The radioactivity profile of cytoplasmic RNA displays an enhanced labelling in the 4S region as an expression of 4S RNA transport from the nucleus to the cytoplasm²¹. There is also a slightly increased radioactivity level in the position of the rRNA components, but there is no significant increase in labelling in the range above 28S. Thus, in spite of the fact that a considerable reduction of labelled chromosomal heterogeneous RNA takes place during actinomycin D chase, there is no corresponding increase of label either in nuclear sap or in the cytoplasm. Practically no rapidly labelled high molecular weight RNA moves out from the nucleus to the cytoplasm if labelling for 25 min is combined with 65 min actinomycin D chase.

It is yet not understood whether nascent RNA chains blocked by actinomycin D are detached and then broken down or if they are broken down without leaving the transcription sites. Electron micrographs of nucleolar DNA, containing nascent preribosomal RNA in 'Christmas tree' formation, show a random loss of incomplete RNA molecules during actinomycin D treatment irrespective of the

length of molecules (Mr F. Trendelenburg and W. W. Franke, unpublished.) A random and nonphysiological release of unfinished RNA chains may be the interpretation of the electrophoretic analyses of heterogeneous chromosomal RNA showing a parallel decay of labelling in the whole spectrum after actinomycin D chase. A labelling period of 25 min before the addition of the drug is sufficiently long, however, for completion of a substantial amount of 4S RNA, and during the subsequent actinomycin D treatment, transport of labelled 4S RNA from nucleus to cytoplasm can be demonstrated.

The electrophoretic analyses of labelled RNA from chromosomes (Fig. 2a), nuclear sap (Fig. 2b) and cytoplasm (Fig. 2c) after 45 min of labelling and after 45 min of labelling plus 45 min of actinomycin D chase are shown in Fig. 2. The pattern of labelled chromosomal RNA after 45 min of labelling shows a bimodal distribution similar to that after 25 min of incubation (Fig. 2a). Whereas the labelling of chromosomal RNA during 45 min of actinomycin D chase decayed 30–35%, the relative distribution of the heterogeneous RNA remained roughly the same as in the control profile. The emergence of a distinct radioactivity peak around the 30S region in the drug-treated glands can be explained by accumulation of preribosomal RNA of nucleolar origin on the chromosomes¹⁵. This appearance of preribosomal 30S RNA on the chromosomes seems to be potentiated by treatment with actinomycin D. The electrophoretic pattern of nuclear sap RNA after 45 min of labelling contains, besides a distinct 4S RNA peak, label distributed rather heterogeneously in the 16–100S range, with a small peak in the 75S region (Fig. 2b). The material distributed between 16–30S is likely to be of ribosomal origin¹⁵. When a normal 45 min pulse is followed by synthesis inhibition for 45 min, the radioactivity profile of nuclear sap RNA exhibits a decrease (30–35%) compared with the normal profile, except for rRNA in the 16–30S range, which is slightly increased. The reduction of label is most pronounced in the 4S and 35–40S regions. The electrophoretic analysis of labelled cytoplasmic RNA shows distinct peaks in the 4S and 18S regions and a small one in the 28S region (Fig. 2c). There is also a minor but significant peak in the 75S region¹⁷. 75S RNA as well as rRNA appears in the cytoplasm somewhat earlier than has been previously described¹⁷. After 45 min of actinomycin D chase the

electrophoretic pattern displays a generally increased labelling in the whole spectrum, although the increase is less in the highest molecular weight range. Distinct peaks can be seen in the 4S region and in the position of the ribosomal 18S and 28S RNA components. An additional rather discrete radioactivity component emerges in the 35–40S range during actinomycin D chase. It can be seen that the reduction of labelled RNA during actinomycin D chase is largest in this range of the profile of nuclear sap RNA. This cytoplasmic 35–40S RNA has characteristic labelling kinetics, and thus this peak is not an artefact due to actinomycin D treatment. A more extensive description of this RNA fraction will be presented elsewhere.

In spite of the lack of release of prelabelled heterogeneous RNA from the chromosomes during synthesis inhibition with actinomycin D (Fig. 1), radioactivity is increased in the high molecular weight range of cytoplasmic RNA (Fig. 2). This means that prelabelled nonribosomal RNA is being transported from the nuclear sap. In fact, more than 80% of the increase in radioactivity associated with the nonribosomal cytoplasmic RNA in the 16–100S range can be accounted for by the decrease of label in the same range of the nuclear sap profile. Only 30–35% of the prelabelled nuclear sap RNA, however, disappears during 45 min of actinomycin D chase.

I have found that after 25 min incorporation of radioactive precursors into *Chironomus tentans* salivary glands, the chromosomal RNA is labelled, but no appreciable amount of label appears in the nuclear sap and cytoplasm except in the 4S region. During a subsequent actinomycin D chase for 65 min the labelling of heterogeneous chromosomal RNA decreases by 40–50% but the decrease is not accompanied by an increase of label in the nuclear sap and cytoplasm except in the 4S range. A labelling period of 45 min is sufficiently long to allow a substantial amount of labelled heterogeneous chromosomal RNA to enter the nuclear sap and cytoplasm. If a labelling period of 45 min is followed by a 45 min actinomycin D chase, an export of nonribosomal high molecular weight RNA from the nucleus to the cytoplasm can be demonstrated.

One could explain the findings of the present work as follows; first, the labelled heterogeneous chromosomal RNA consists mainly of nascent chains or of nascent and finished RNA chains, all bound to the DNA template and, second, the appearance of finished RNA molecules (processed or unprocessed) in nuclear sap before the addition of actinomycin D is a prerequisite for transport of labelled RNA from nucleus to cytoplasm. Although some qualitative aspects of RNA transfer from the nucleus to the cytoplasm can be studied by the pulse-chase technique including actinomycin D, it is definitely not a method of choice for examining turnover rate, processing of rapidly labelled RNA and for quantitation of heterogeneous RNA transfer from nucleus to cytoplasm. This is because actinomycin D interferes with the completion and release of heterogeneous chromosomal RNA, and the contribution of nonreleasable label to the total labelled heterogeneous nuclear RNA cannot be determined in most cell systems.

Defective DNA repair in Fanconi's anaemia

FIBROBLASTS from patients with Fanconi's anaemia (FA) show increased susceptibility to transformation *in vitro* by SV40 virus¹, as well as spontaneous chromosome breakage². Chromosomal instability has also been observed in cultured peripheral blood lymphocytes and in bone marrow cells³. More recently, Sasaki and Tonomura⁴ demonstrated an increased susceptibility of lymphocytes from patients with FA to chromosome breakage by DNA cross linking agents. These results were interpreted as an indication that FA cells are defective in some DNA repair mechanism.

The studies we report here demonstrate that DNA repair by fibroblasts from a patient with FA is defective and suggest that the abnormality is due to a defect in the excision of DNA lesions. This is probably the result of a deficiency of a specific exonuclease.

The first step in the removal of ultraviolet-induced thymidine dimers or any other DNA damage which does not directly produce breaks in the DNA is the production of a single-strand scission by an endonuclease⁵. This can be demonstrated in normal cells by observing the shift in sedimentation of DNA, 90 min after irradiation with ultraviolet light, from the normal distribution to one in which the small DNA fragments sediment at a much slower rate (Fig. 1a). Figure 1b shows the results of incubating the cells for 10 h after they have been irradiated. A fraction of the DNA shifted back toward the normal sedimentation peak, suggesting that repair was taking place.

There was also a reduction in the S value of DNA in FA cells as a result of ultraviolet irradiation. Figure 1a shows that 90 min after FA cells were subjected to ultraviolet irradiation of 250 ergs mm⁻², the major peak disappeared and the DNA sedimented at the lower sedimentation rate characteristic of the light DNA occurring in FA cells in the absence of ultraviolet irradiation. Incubation of FA cells for 10 h after ultraviolet irradiation (Fig. 1b) did not result in any shift back towards the normal sedimentation pattern. These results suggest that the cells can produce single strand breaks after ultraviolet irradiation,

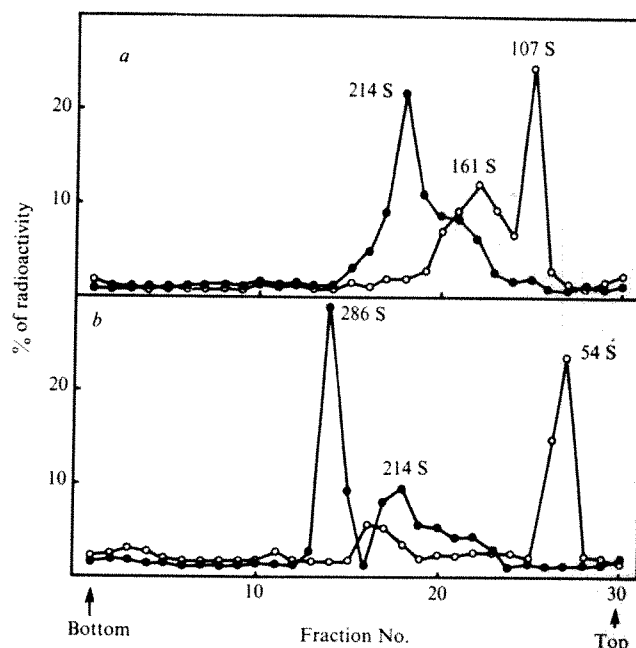

Fig. 1 Alkaline sucrose gradient sedimentation of labelled DNA from normal (●) and Fanconi's anaemia (○) fibroblasts (American Type Culture Collection No. HG261) after ultraviolet irradiation: *a*, 90 min after 250 ergs mm⁻²; *b*, 10 h after 250 ergs mm⁻². Cells were grown as a monolayer in minimal Eagle's medium with Earle's balanced salt solution supplemented with 10% foetal calf serum (inactivated), kanamycin (100 µg ml⁻¹), and non-essential amino acids. Two days after seeding the medium was replaced by medium containing ³H-thymidine (0.2 µCi ml⁻¹, specific activity 50 Ci mmol⁻¹, Amersham/Searle), and the cultures were grown for 18-22 h at 37° C in an atmosphere of 5% CO₂-95% air. The monolayer cells were washed three times with calcium and magnesium-free phosphate-buffered saline (PBS) and scraped or trypsinised from the flasks. The cell suspension was washed again and diluted to 5 × 10⁵ cells per ml with PBS. The sucrose solution was made with nuclease-free crystal sucrose (Schwarz/Mann) in double distilled water containing 0.9 M NaCl, N NaOH and 1 mM EDTA-disodium, pH 12.2. Linear sucrose gradients in polyallomer centrifuge tubes (36 ml) with a concentration of 5% sucrose at the top and 20% at the bottom were generated by a Beckman density gradient former. At the top of each gradient 0.3 ml of 0.5 N NaOH were overlaid and 0.3 ml of cell suspension (5 × 10⁵ cells per ml labelled with ³H-thymidine in PBS) was gently pipetted in. The tubes were kept for 2 h at room temperature and at 4° C for 16 h. The gradients were centrifuged at 23,000 r.p.m. for 2 h at 10° C in an SW 27 rotor of a Spinco Model L3-50 (Beckman) ultracentrifuge. Fractionation of the gradients was performed with a hypodermic needle pierced through the bottom of the tube and fractions were collected with a peristaltic pump through an automated fraction collector. Each fraction was precipitated by addition of 5% trichloroacetic acid, collected on an MF Millipore filter. Radioactivity on the dried filters was determined by transfer to 10 ml of a toluene based scintillation cocktail which was counted in a Beckman LS 250 liquid scintillation spectrometer.

tion, indicating the presence of an endonuclease, but cannot complete the repair process.

After cells have been irradiated with ultraviolet light and produce a single strand break (nick) near the induced pyrimidine dimers, the next step in the repair process involves the unwinding of the two strands in the neighbourhood of the nick and the polymerisation of a new strand of DNA complementary to the intact member of the DNA double helix⁵. This polymerisation can be demonstrated by unscheduled DNA synthesis detected autoradiographically by the incorporation of ³H-thymidine into the cellular DNA or, more specifically, by repair replication as assayed by Cleaver⁶. Unscheduled DNA synthesis in FA cells is comparable with that which occurs in normal cells (Fig. 2).

The incorporation of ^3H -thymidine, as indicated by the number of grains over the nuclei of the irradiated cells, increased as a function of the dose of irradiation and there was no distinguishable difference between the relative number of grains in FA cells and normal cells.

Unscheduled DNA synthesis was induced by treating FA cells with 4-nitroquinoline-N-oxide (4NQO), a carcinogen known to induce unscheduled DNA synthesis and replication repair synthesis in human cells (our unpublished studies). This agent induced no unscheduled DNA synthesis in the cells of patients with xeroderma pigmentosum^{7,8}, suggesting that it does not produce single-strand breaks directly. The fact that it induced unscheduled synthesis in FA cells suggests that they can make single-strand scissions after treatment with 4NQO as well as after irradiation with ultraviolet light.

To complete the repair of ultraviolet-induced DNA damage, it is necessary for the damaged strand to be excised so that the newly synthesised strand can be linked by phosphodiester bonds to the end of the remaining portion of the damaged strand. This is generally considered to be the function of a specific exonuclease. Exonucleases which seem to be specific for ultraviolet-induced damage have been isolated from cells⁹. The excision of thymidine dimers can be demonstrated by measuring the dimer content of irradiated DNA immediately after irradiation and again after irradiated cells have been incubated for a repair period. After the irradiation the number of dimers detectable in the DNA diminishes⁵. Figure 3 shows the results of an experiment in which normal cells were exposed to various doses of ultraviolet light and the number of dimers was determined in the DNA immediately and after a 24 h incubation. The number of thymidine dimers was a function of the ultraviolet dose over the range examined and after 24 h a large fraction of the dimers had been removed from the DNA of the normal cells.

When FA cells were subjected to the same doses of ultraviolet irradiation, the number of dimers measured immediately was essentially the same as seen in normal cells (Fig. 3). During a 24 h postirradiation period, however, FA cells could remove only a small fraction of the induced dimers. This difference was not apparent at ultraviolet doses below 150 ergs mm^{-2} , possibly because the FA cells could remove during the 24 h incubation,

Fig. 2 Effect of ultraviolet irradiation on grain count of normal fibroblasts (●) and FA fibroblasts (○). Cells on coverslips were rinsed with PBS and pulsed with ^3H -thymidine ($2 \mu\text{Ci ml}^{-1}$, 50 Ci mmol^{-1}) for 1 h to identify cells in S phase. After ultraviolet irradiation at various doses, cells were exposed to ^3H -thymidine again for 2 h. Autoradiographs were prepared and the average grain count over lightly labelled cells was determined after a 2-week exposure.

Fig. 3 Comparison of excision of thymine-containing pyrimidine dimers from ultraviolet-irradiated, ^3H -thymidine-labelled normal human fibroblasts and fibroblasts from a patient with FA: normal human fibroblasts immediately after irradiation (●) and 24 h after irradiation (○); FA cells immediately after irradiation (★) and 24 h after irradiation (☆). Cells growing in a glass Petri dish were labelled with ^3H -thymidine ($5 \mu\text{Ci ml}^{-1}$, 50 Ci mmol^{-1}). Cultures were then rinsed with PBS and irradiated with ultraviolet light at a dose rate of $10 \text{ ergs mm}^{-2} \text{ s}^{-1}$. After irradiation some cultures were fixed immediately with perchloric acid in the cold. Others were rinsed with PBS and allowed to grow for 24 h and then fixed. 5×10^6 cells were scraped into a Pyrex tube ($7.5 \times 100 \text{ mm}$) and precipitated with 5% trichloroacetic acid. The precipitate was washed, dried and hydrolysed in 0.2 ml of 98% formic acid by heating at 175°C for 2 h. The hydrolysates were spotted on a sheet of Whatman No. 1 paper for two-dimensional chromatography and the percentage of radioactivity was measured. This method cannot distinguish the difference between normal and FA with an ultraviolet dose below 150 ergs mm^{-2} . Either FA cells demonstrate normal excision at a low dose of ultraviolet light or the method is not sufficiently sensitive to detect it.

the relatively small number of dimers produced by lower doses of ultraviolet light. This indicates that although the FA cells could produce the endonucleolytic scission as the first step of the repair process and could polymerise nucleotides to repair or replace the damaged strand of DNA, they were deficient in the ability to remove the strand of DNA bearing the abnormal thymine dimers.

We have demonstrated that FA cells possess most of the functions required for the repair of ultraviolet-induced DNA damage. They can produce single strand scissions in response to pyrimidine dimer induction and they can polymerise nucleotides into a new complementary strand to replace that damaged portion of the DNA molecule. However, they seem to be deficient in an exonuclease function which removes the damaged strand of DNA after the endonucleolytic strand scission has been made. It is interesting that the FA cells studied seem capable of rejoining X-ray-induced strand breaks, suggesting that ligase activity is present (our unpublished data).

Regan *et al.* have stated that FA cells can normally excise ultraviolet-induced pyrimidine dimers¹⁰. The reason for the discrepancy between their results and ours is not clear, but may relate to their use of lower doses of ultraviolet irradiation. Our studies have demonstrated that a dose of at least 150 ergs mm^{-2} is necessary to demonstrate a difference between normal and FA cells. Thus, although FA cells do not seem to be as sensitive to ultraviolet light as xeroderma pigmentosum cells, they are more sensitive than normal cells. In fact, our results

indicate that exonuclease activity is not completely lacking. This may also explain the lack of ultraviolet-induced skin cancer in these patients.

Another possibility is that different cell lines were studied. Our studies have all been performed on one strain of fibroblasts (American Type Culture Collection) originally obtained from a patient with FA. Therefore we cannot yet conclude that the findings are characteristic of all FA cells. Nevertheless, they are interesting since they demonstrate a failure of DNA repair at a site not previously described.

Introduction of mouse L cell nucleus into heterologous mammalian cells

HARRIS¹ first achieved the introduction of a chick erythrocyte nucleus into other nucleated mammalian cells, without any detectable incorporation of chick erythrocyte cytoplasm, using inactivated Sendai virus. Since then chick erythrocyte nuclei have provided a way of investigating the genetic regulation of nuclear synthetic activities in the presence of a genetically disparate cytoplasm and nucleus^{2,3}. Similar studies with nuclei from other mammalian cells have been presented, however, by the lack of a method for obtaining nuclei suitable for introduction into another type of cells.

When Carter⁴ first reported the enucleation of mammalian cells by the drug cytochalasin B, a metabolic product of the fungus *Helminthosporium dematioides*, he predicted that the separated nuclei and the enucleated cytoplasm might be used in nuclear exchange experiments. Since then the fusion of enucleated cells of one type with nucleated cells of another type has been achieved^{5,6}. During our earlier electron microscopic studies^{7,8} on the enucleation of mouse L cells with cyclochalasin B we observed that the nucleus ejected from the cell carried along with it a very thin rim of cytoplasm within the plasma mem-

brane. As the fusion of cells induced by the inactivated Sendai virus is believed to involve the fusion of two plasma membranes it seemed possible to fuse the nuclei obtained from cytochalasin B-treated cells with other types of cells. Here we report the introduction of mouse L cell nuclei, prepared by treating the cells with cytochalasin B, into nucleated human HeLa cells with the aid of inactivated Sendai virus.

Mouse L cells (clone 929) used for obtaining the nuclei were grown on the surface of plastic Petri dishes as monolayers in Eagle's medium containing 15% calf serum, 100 units ml⁻¹ of penicillin and 100 µg ml⁻¹ of streptomycin (GM). The cultures were prelabelled with tritiated thymidine; before use, 100 µCi of ³H-thymidine was added to the cultures every 6 h for a total of 42 h. This resulted in the labelling of almost every cell. Such prelabelled sheets of L cells were treated with cytochalasin B to bring about enucleation^{4,9}. The method used was a modification of the technique described by Prescott *et al.*⁹.

Briefly, it consisted of inserting plastic Petri dishes carrying adherent cell sheets into stainless steel centrifuge tubes. The tubes contained BM supplement with 1 µg ml⁻¹ of amphotericin B and 5 µg ml⁻¹ cytochalasin B (Serva, Feinbiochemica, Heidelberg) predissolved in dimethylsulphoxide (DMSO) at a concentration of 1 µg ml⁻¹. Centrifugation at room temperature for 45 min at 10,000g resulted in almost complete enucleation. The Petri dishes were inverted on the bottom of the test tubes (cell side facing down) so that the plane of cell layer was at an angle of 37° ± 2° to the line of centrifugal force.

The addition of amphotericin B to the reaction mixture facilitated the cytochalasin B-induced enucleation process (unpublished results). The sediment at the bottom of the centrifuge tubes consisted mainly of L cell nuclei. Figure 1 shows the enucleation phenomenon. Observed under the electron microscope the extruded nuclei reveal the presence of a thin rim of cytoplasm around them containing ribosomes, very rarely one or two mitochondria and a few fragments of endoplasmic reticulum. It was itself enclosed by a plasma membrane (Fig. 2).

The L cell nuclei were introduced into human HeLa cells maintained in GM. These cells (10⁶) were seeded in Leighton tubes containing glass coverslips and incubated at 37° C. After 48 h, the culture medium was removed and the cell sheet was layered with a thin suspension of L cell nuclei and 500 haemagglutinin units of Sendai virus (inactivated with 0.06% β-propiolactone¹⁰). The cultures were

Fig. 1 L cell enucleation by cytochalasin B. a, during extrusion from the cells, nuclei are connected to the cells by thin cytoplasmic processes (arrows); b, Nuclei ejected from the cell cytoplasm show prominent nucleoli (arrows). Giemsa stain (×528).

kept in the cold for 10 min followed by incubation at 37° C for 1 h. Fresh GM was added after washing off the excess nuclei and inactivated virus. Some of the coverslips were processed immediately for autoradiography but other coverslip cultures were incubated further and examined at regular intervals.

The presence of labelled L cell nuclei near the unlabelled HeLa cell nucleus (Fig. 3b) provided unequivocal evidence of the introduction of the L cell nuclei into HeLa cells. Approximately 10% of the cells were binucleate heterokaryons (Fig. 3a), the remaining being multinucleate heterokaryons, homokaryons or mononucleate HeLa cells. (Heterokaryons and somatic cell hybrids are the terms generally reserved for cells arising following the fusion of two or more genetically different types of cytoplasm and nuclei and as such have been used here.)

The presence of L cell membrane properties on the cell surface of heterokaryons provided evidence for the effective functioning of the introduced L cell nucleus. Mouse species-specific antigens were detected by the mixed haemadsorption technique^{11,12}. L cells carry on their surface a type C virus-induced antigen and this was detected on heterokaryons by indirect membrane immunofluorescence using anti-Moloney virus serum as described by Fenyo *et al.*¹³. HeLa cells showed complete absence of these surface properties.

The multinucleate heterokaryons and homokaryons gradually disappeared from the culture within 1–2 weeks, leaving behind either mononucleate hybrid cells or HeLa cells. The recognition of hybrid cells presented no problem as their cytoplasm was not well spread and the nucleus was frequently larger than the HeLa cell nucleus. These hybrids continue to express some of the L cell surface traits. A detailed account of the studies on the karyotypic analysis of these hybrids and their antigenic properties will be reported elsewhere.

The possible contamination of these hybrids with a small amount of L cell cytoplasm, which remains attached to the L cell nucleus, cannot be excluded. It seems unlikely, however, that such a small amount of cytoplasm in the hybrid will have any controlling effect on the expression of nuclear functions as it would be rapidly diluted out in the hybrid progeny cells.

Fig. 2 Electron micrographs of the ejected L cell nuclei. *a*, Ejected L cell nucleus, *n*, surrounded by a thin fragment of the cell cytoplasm, *cy*, containing some of the cytoplasmic organelles ($\times 8,200$); *b*, Enlarged portion of the ejected L cell nucleus showing a distinct plasma membrane (arrows) surrounding the cytoplasmic fragment, *cy*, which in turn encloses the nucleus, *n* ($\times 24,000$).

Fig. 3 *a*, Phase contrast photomicrograph of a HeLa cell containing the introduced large L cell nucleus (arrow). Note the relatively small HeLa cell nucleus (long arrow) ($\times 1,125$); *b*, Autoradiograph of a heterokaryon containing unlabelled HeLa cell nucleus (long arrow) and the labelled L cell nucleus (arrow) within HeLa cell cytoplasm. The L cells were grown in ³H-thymidine before the nuclei were removed and introduced into HeLa cells ($\times 1,418$).

Our demonstration of the introduction of L cell nuclei into HeLa cells makes possible the introduction of isolated mammalian cell nuclei into enucleated cells, thereby allowing true nuclear exchange experiments which have been previously impossible with mammalian cells.

Effect of β_2 microglobulin antibody on effector function of T-cell mediated cytotoxicity

A MEMBRANE fragment of human lymphoid cells obtained by papain digestion has been found to be composed of two subunits which differ in molecular weight^{1,2}. The heavy molecular weight subunit (33,000 daltons) carries the HL-A serologically defined (SD) antigens while the light molecular weight subunit (11,000 daltons) carries antigenic determinants reacting with antiserum directed against β_2 microglobulin (β_2m)³⁻⁶. Treatment of human lymphocytes with antisera directed against the HL-A SD antigens results in capping of these antigens⁷; addition of β_2m antibody to lymphocytes will likewise cause capping of the HL-A SD antigens^{8,9}. Furthermore, activation of lymphocytes in mixed leukocyte culture (MLC) can be inhibited by β_2m antibody^{9,10}. These data suggested to the investigators^{9,10} that the HL-A subunit and/or the β_2m subunit may be part of the same receptor complex of the T lymphocyte. This concept is supported by the recent studies of β_2m demonstrating extensive homology between β_2m and the constant regions of the heavy chain (and the light chain) of immunoglobulin IgG^{11,12}. Consequently β_2m was thought to have a recognition function similar to that of immunoglobulin.

Lymphocytes stimulated by allogeneic cells in MLC specifically destroy target cells autologous to the stimulating cells¹³. Effector cells generated in MLC are thought to be thymus-derived (T) cells¹⁴. We wish to report here that preincubation of MLC-generated effector cells with β_2m antibody has no effect on their ability to specifically recognise and destroy target cells autologous to the sensitising cells. Preincubation of target cells with anti β_2m antibody resulted in enhancement of cytotoxicity due to an antibody-dependent cell-mediated cytotoxicity.

The purification of lymphocytes, generation of effector cells in MLC and preparation of ⁵¹Cr-labelled target cells has been previously described^{13,15}. Anti- β_2m antiserum was prepared in New Zealand rabbits¹⁶. All sera were decanted by heating at 56°C for 30 min. The anti- β_2m was rendered specific by absorption with lyophilised human serum, lyophilised urine of normal individuals and erythrocyte membranes. The antiserum gave a single precipitin line on Ouchterlony immunodiffusion plates and immunoelectrophoresis with pure β_2m and with sera from patients containing large amounts of β_2m . Addition of purified β_2m to the antiserum completely eliminated the enhancement of cytotoxicity when the target cells were

preincubated with β_2m antibody. For preincubation of effector or target cells, a volume of 50 μ l of undiluted β_2m antiserum or normal rabbit serum was added to 0.1 ml of lymphocytes (2×10^6) and incubated at 4°C for 1 h. The cells were centrifuged (400g) for 10 min, washed three times in tissue culture media 199 (TC-199) and used immediately in the cytotoxicity reaction. The target cells were labelled with ⁵¹Cr before incubation with the β_2m antiserum.

The cytotoxicity reaction was conducted in microculture plates with 1×10^6 effector cells and 1×10^4 target cells contained in a total volume of 0.2 ml TC-199 supplemented with 20% human frozen pooled plasma. The plate was incubated for 4 h at 37°C in an atmosphere of 5% CO₂ and 95% air. Then the plate was centrifuged, an aliquot removed and ⁵¹Cr release monitored as previously described¹⁵. All reactions were done in triplicate.

As demonstrated in Table 1, lymphocytes of individual A were sensitised in MLC to the histocompatibility antigens of individuals B or C. The degree of stimulation was measured by ³H-thymidine incorporation. The allogeneic combinations AB or AC produced good stimulation while the autologous combination (AA) produced relatively little ³H-thymidine incorporation. After 6 d, ⁵¹Cr labelled lymphoblasts were added to the responder cells (now termed effector cells). Significant ⁵¹Cr release was obtained when the target and stimulator cells were autologous (AB/B). When the stimulator and target were allogeneic (AC/B) no ⁵¹Cr release was demonstrated. In addition, when the responder-stimulator combination was autologous (AA/B) or when the target and responder cells were autologous (AB/A) no ⁵¹Cr release was obtained. Preincubation of the sensitised effector cells with the β_2m antiserum had no significant effect on the ability of the cells to specifically destroy target cells. Preincubation of the target cells with the same concentration of anti- β_2m resulted in an enhancement of the cytotoxicity, which was due to an antibody-dependent cell-mediated type of cytotoxicity first described by Moller¹⁷. In this type of cytotoxicity unsensitised lymphocytes perform equally well as effector cells. As demonstrated in Table 1, unsensitised lymphocytes (A) used as effector cells against the target cell (B) produced excellent ⁵¹Cr release. The β_2m antiserum was used in the experiments reported here at a final dilution of one to three. Complete inhibition of MLC was produced with this same antiserum at a dilution 1 to 50¹⁸.

Antisera directed against either β_2m or the SD antigens of the HL-A complex inhibit the MLC. In addition, β_2m and the SD antigens have been shown to be associated on the lymphocyte membrane. These facts, in addition to the homology between β_2m and the constant domains of IgG, have led several investi-

gators to suggest that the β_2m subunit and the alloantigenic subunit are closely associated with the lymphocyte receptor^{9,10}. Convincing evidence has been put forward demonstrating that the genetic loci responsible for stimulation in MLC are separate from the HL-A loci coding for the SD antigens²¹⁻²⁵. Evidence from several laboratories^{19,20} have suggested that effector cells generated in MLC recognise only SD antigens. Therefore, the receptor sites on the T cells responsible for cell destruction are presumably directed toward the SD antigens. Our data suggest that the receptor sites responsible for the recognition do not seem to be associated with β_2m . In addition, Poulik *et al.* have demonstrated that there is no association between β_2m and surface immunoglobulin on the membrane of human B cells⁸. One cannot rule out the possibility that the receptor which recognises the gene product of the MLC loci is of a different type (that is, associated with β_2m) than that responsible for cell destruction.

The relationship between β_2m and the antigen on the target cell responsible for cell mediated cytotoxicity is unclear because of the interference by the antibody-dependent cell-mediated cytotoxicity. This problem can be eliminated by using F(ab)₂ of the β_2m antibody in the cytotoxicity reaction. Experiments toward this end are in progress.

This investigation was supported by grants from the US Public Health Service, Kidney Foundation of Michigan and Michigan Heart Association.

New alloantigen genetically linked to the major histocompatibility locus of the mouse

THE mouse *H-2* locus and its genetic homologue, the *HL-A* locus in man, are much more complex than originally envisaged, and are now referred to as the major histocompatibility complex (MHC)¹. Transplant rejection is more closely correlated with mixed lymphocyte reaction (MLR) than with tissue typing²⁻⁶ and in addition to an *MLR* region in the MHC other regions are of obvious importance in the context of recognition, for example the immune responsiveness regions (*Ir*)^{7,8}. The only gene products of the MHC so far characterised are those recognised serologically by 'tissue typing' antisera, that is, *H-2* antigens and their homologues in other species. These products are not the only substances involved in the fate of allografts; indeed sensitisation against an allograft seems to require MLR differences although serologically detected components have an, as yet undefined, role in the effector arc of rejection⁹⁻¹¹. Though there are suggestions that MHC gene products other than *H-2* (*HL-A*, and so on) may be primarily involved in graft rejection¹², the only *in vivo* studies pointing strongly in that direction were carried out in the rat enhancement model¹³. In these studies rat heart allografts were passively enhanced by alloantisera from which Ag-B (the *H-2* homologue in rats) antibodies had been removed by absorption with appropriate red blood cells (RBC), which suggests a role for antibodies directed against other products of the MHC.

MLR and graft-versus-host reactions may occur in the absence of serological differences at the MHC³⁻⁵ and since genetically engineered situations have led to the detection of new T- and new B-cell associated antigens in the mouse system¹⁴⁻¹⁷, great importance attaches to the definition of other products controlled by the MHC. Here we describe some properties of a gene product found on thymus-derived lymphocytes and determined by a gene near the *K-end* of the MHC.

In a complement-dependent cytotoxicity test, an anti-serum (kxb anti-d) prepared in (B10.Br×C57BL/6)_{F1} mice by immunisation with DBA/2 spleen cells showed, after absorption with B10.D2 or BALB/c (*H-2^b*) RBC, only 25-30% ⁵¹Cr release with B10.D2 lymph node target cells. This target cell is used to provide a congenic system; hence genetic markers not related to the MHC remain undetected. A membrane suspension from BALB/c spleen cells was solubilised by controlled papain digestion, fractionated on DEAE Sephadex-A50, and six peaks eluted stepwise at (1) 0.05 M, (2) 0.1 M, (3) 0.15 M, (4) 0.2 M, (5) 0.25 M and (6) 0.5 M NaCl were collected¹⁸. Fractions 3 and 4 contained the *H-2* activity (*H*-antigens). These six fractions when monitored with the RBC absorbed antiserum, showed a totally different pattern: only fraction 5, eluted with 0.3 M NaCl showed specific inhibition of immune cytotoxicity (160 ID₅₀ units mg⁻¹). An included fraction corresponding

Fig. 1 Polyacrylamide gel electrophoresis. *a*, Serological profile of a highly purified antigen fraction. Gel slices (1 mm) were eluted, dialysed and freeze dried, and the material was tested for alloantigenic activity by inhibition of complement-dependent lysis (^{51}Cr release). For this purpose an H-2 alloantiserum was first absorbed with red blood cells from H-2^d mice¹³. Inhibition of immune cytotoxicity (O—O). The position where H-antigens would be found in the same system¹⁹ is indicated by the horizontal bar. *b*, Staining pattern of the new alloantigen; migration is from - to +. The discontinuous system used in the present work has been described in detail previously^{18,19}. *c*, Isotachopheresis of the same fraction, performed as detailed elsewhere^{18,19}. pH measurements were carried out in the gel eluates (1 mm fractions). The position (pH) where H-2 antigens would appear but which were removed by previous DEAE chromatography, is indicated by arrows. A specificity check was performed in parallel (not shown) using a RBC-absorbed B10.D2 anti-B10.A antiserum with B.10A target cells. Inhibition of immune cytotoxicity (O—O); pH (●—●). FRC=full release control, indicating 100% ^{51}Cr release.

to an apparent molecular weight of 36,000 (1,700 ID₅₀ units mg^{-1}) was isolated by Sephadex G-100 chromatography. On SDS electrophoresis this fraction migrated with an average M_r of 34,000. After elution from polyacrylamide gel electrophoresis, a serologically active peak was obtained at a relative migration value of about 0.67, corresponding to a single band in a stained gel run in parallel. For comparison, H antigens migrated in the same system with R_F values of about 0.4. A further purification on DEAE Sephadex-A50 provided an active fraction with an electrophoretic and serological pattern as depicted in Fig. 1*a* and *b*. Fig. 1*c* shows the pI (pH 4.6) of this substance compared to about pH 5.0 (H-2.31) and 5.4 (H-2.4) for H antigens. Furthermore this material contains 0.57 mol SH per mol protein as determined by DTNB (ref. 20).

Previous results indicated that desorption of papain-solubilised H-antigens reacting with H-2.34 antisera occurred later than the main H-2 fraction on ion exchange chromatography²¹. The reactivity of the RBC-absorbed H-2 antiserum with the new antigen was, however, unimpaired after the antiserum had been further absorbed with DBA-1 (H-2^a) lymph node cells, thus eliminating H-2.34. A genetic linkage to the MHC is clear since the antiserum used was obtained from (B10.Br \times C57BL/6)_{F1} mice providing congenicity with the B10.D2 target cells.

When tested for *D-end* activity, two antisera ($K^kD^d \times K^bD^b$) anti K^dD^d (Fig. 2*a*) and ($K^kD^d \times K^{bc}D^{bc}$) anti K^dD^d (Fig. 2*b*) showed no residual titre using K^kD^d or K^dD^d target cells respectively. This indicates that the residual cytotoxicity observed in Fig. 2*b* for the H-2.31 antiserum and in Fig. 2*c* is a *K-end* reaction and that the antigenic product is controlled by gene(s) located near the *K-end* of the MHC.

It is of particular significance in this context that the *Ir*

region is in the close vicinity of the *K-end* of the MHC⁸. *Ir* gene products have been considered to be candidates for T-cell recognition structures⁷. We would like to propose the term 'R-antigen' for these substances in contrast to

Fig. 2 An antiserum (H-2.4, 10, 13, 31, 34, 40, 41, 42, 43, 44) was prepared by immunisation of $K^dD^d \times K^bD^b$ F_1 hybrids with (K^dD^d) mice. Titres obtained in cytotoxicity test (^{51}Cr release) using *a*, B10.A (K^dD^d) target cells with the H-2 antiserum described above (AS 73/5) after absorption with DBA/1 (K^dD^d) lymph node cells (which removes H-2.13, 34), (O—O) and with AS 73/5 absorbed with B10.D2 (K^dD^d) red blood cells (removing the remaining H-2 specificities), (●—●); *b*, B10.D2 target cells with H-2.4 (—) and H-2.31 (---) antisera before (O) and after (●) RBC absorption. *c*, Serological pattern of AS 73/5 tested against B10.D2 target cells before (O—O) and after (●—●) absorption with B10.D2 or BALB/c RBC and after further absorption with DBA/1 lymph node cells (●—●).

Fig. 3 DE-52 chromatography pattern of a thymus cell membrane preparation solubilised with papain (1:100, 1 h, 37° C) and previously run on a P-300 Biogel column. The DEAE column was developed with a linear NaCl gradient (0.0 M–0.3 M) in a total volume of 750 ml 0.05 M Tris-HCl buffer, pH 8.0. Fractions of 5 ml were collected. The H-2 serological activity (●—●) was measured by inhibition of complement-mediated cytotoxicity (^{51}Cr release) and is shown to be confined to the region of pool B. Pools (A to E) were made as indicated. Note the magnitude of pool D. Using an H-2^d thymus preparation the specific activity (ID₅₀ units) obtained with the RBC absorbed antiserum for pool D was 2.5 times (380 U mg⁻¹) the activity recovered from comparable spleen material prepared under identical conditions.

the H antigens mentioned previously. An association of the present antigen with T cells comes from two sources. First, target lymph node cells treated with anti- θ serum, which gave a 50% kill, did not lead to the two-fold titre increase expected if the antiserum were B-cell reactive. Second, when thymocyte membranes were extracted and fractionated by ion exchange chromatography as described previously²², the major component present (pool D) had identical physicochemical and serological properties to the antigen isolated from spleen cells (Fig. 1b and Fig. 3). This despite the fact that under normal conditions thymocytes are not a target for complement-mediated lysis by this antiserum. Thymocytes therefore contain the antigen (tentatively called R1.1) which is exposed, however, only on extrathymic cells. Recently several new specificities not attributable to *D*- or *K*-end gene products have been described (see refs 14, 16). Whereas these seem to be B-cell features, the antigenic products we describe here has T-cell affinities. Like other MHC gene products, the biological significance of this new substance remains to be determined.

We thank Dr G. J. O'Neill for providing a congenic (A/ θ AKR anti A/J) theta antiserum. The assistance of S. Doel, M. Evans and J. Quigley is acknowledged. H-2.4 and H-2.31 antisera were provided by the H-2 alloantiserum bank of the Transplantation Immunology Branch, National Institutes of Health, Bethesda.

Generation of antistreptolysin O activity in contaminated sera

THE ability to lyse erythrocytes of reduced streptolysin O, produced by strains of Lancefield's group A streptococci apparently results from attachment to membrane cholesterol. Cholesterol in aqueous emulsion will inhibit streptolysin activity at concentrations of about 1.0 $\mu\text{g ml}^{-1}$ (ref. 1). Sera contaminated with bacteria can occasionally give false positive tests for anti-streptolysin antibody but the underlying mechanism has never been defined. We have excluded the possibility that bacterial contamination leads to release of free cholesterol from either ester-bound or protein-bound cholesterol by showing that (1) cholesterol added to contaminated sera showing positive antistreptolysin activity is bound to the same extent as in normal serum, and (2) that ultrafiltrates of such contaminated sera do not contain free cholesterol. Therefore it seemed likely that bacteria in serum might release proteolytic enzymes which would cleave the streptolysin molecule. But the studies reported here indicate that the system is more complex.

Organisms were subcultured from single colonies on agar plates into 1.0 ml amounts of a horse serum-nutrient broth mixture 2:3 v/v. After incubation at 37° C for various periods, cultures were serially diluted in phosphate-buffered saline (0.15 M; pH 6.5) and antistreptolysin activity measured². Results were expressed as that dilution of culture which gave 50% lysis of added human erythrocytes in the presence of 1.0 IU of streptolysin. Table 1 shows the distribution of positive activity in a number of common genera of microorganisms.

Most strains of *Pseudomonas* were positive (90%). Coagulase positive staphylococci showed an 86% positive rate as distinct from 32% for *Staphylococcus albus*. Strains of Enterobacteriaceae such as *Escherichia coli* and *Proteus* species were uniformly negative as were bacillus species, *Haemophilus*, streptococci, pneumococci and *Candida* species. One positive strain of *Neisseria catarrhalis* was detected and one positive strain of *Clostridium histolyticum*. Staphylococcal strains gave positive results with both aerobic and anaerobic cultures. In all cases positive activity appeared slowly after 36–48 h and was maximal after 4–6 d incubation.

Investigation showed that serum is essential, broth cultures themselves having no antistreptolysin activity. Concentrations of serum less than 2.0% gave poor results,

activity increasing with increasing amounts of serum to an optimum of 40–50%. Beyond this, activity was often reduced, but it seems that this may be related to a reduction in the number of organisms in the cultures. The findings suggest that certain organisms are stimulated by a serum substrate to form an inducible enzyme which converts the substrate to an activated form capable of destroying or of inhibiting the action of streptolysin O. The addition of positive serum-broth filtrates to aliquots of fresh normal serum results in generation of new activity in the added serum. As well as lacking the active principle, broth filtrates do not contain enzyme as shown by their inability to generate activity when added to fresh serum. Preliminary tests have located the active serum fraction in the alpha-1 globulin region but it has not yet been possible to separate the enzyme from serum components. The enzyme, serum substrate and active factor seem to be heat stable at 60° C for at least 2 h. Horse, sheep, human and rabbit sera all gave positive results although sheep serum was slightly less effective.

Table 1 Distribution of antistreptolysin activity in microorganisms. Cultures were tested daily for up to 28 d

Organism	No. tested	No. and percentage showing antistreptolysin activity at 1/100 or greater dilution of culture	Reciprocal of mean dilution showing 50% haemolysis
<i>Staph. pyogenes</i>	69	59 (86)	1,600
<i>Staph. albus</i>	25	8 (32)	1,600
B-haemolytic streptococci	14	0 (0)	—
Pneumococci	17	0 (0)	—
<i>Haemophilus sp.</i>	10	0 (0)	—
<i>Neisseriae sp.</i>	12	1 (8.3)	200
<i>Bacillus sp.</i>	16	0 (0)	—
<i>Proteus sp.</i>	25	0 (0)	—
<i>E. coli</i>	58	0 (0)	—
<i>Pseudomonas sp.</i>	92	83 (90)	1,200
<i>Clostridium sp.</i>	13	1 (7.6)	800
<i>Bacteroides</i>	8	0 (0)	—
<i>Candida sp.</i>	19	0 (0)	—

There is evidence that normal serum contains an inhibitor of the active serum factor produced as above, since active serum-broth filtrates of 4 d cultures added to aliquots of fresh serum gave levels of activity after 5–6 h which were much below that expected from the dilution factor. In each case this was followed, after 2–3 d incubation at 37° C, by a rise in the active serum factor to a level some four to five times greater than in the original 4 d cultures. But addition of young broth cultures of positive organisms to filtrates containing high levels of active factor did not reduce these on further incubation. This suggests that in the original 4 d cultures the growing organisms had inactivated a certain percentage of the serum precursor either directly or by activation of some inhibitor system, but that the activated factor itself was not further affected by growing organisms.

Apart from the intrinsic interest of this serum system which may be more complex than outlined, the distribution of positive and negative strains raises problems which clearly may be related to taxonomy as well as providing a possible epidemiological marker. We are investigating whether this property of certain microorganisms relates in any way to other established biochemical activities, and trying to define more clearly the nature of the reacting components, and to show whether the same mechanism operates for different species. Preliminary studies seem to exclude a role for plasminogen activation to plasmin since plasminogen activated with streptokinase does not seem to affect streptolysin activity. Other possible pathways include activation of a kallikreinogen-kallikrein system by the bacterial enzyme or

activation of some complement intermediate compounds.

Antibodies recognise specific structures of triple-helical polynucleotides built on poly(A) or poly(dA)

ANTIGENIC determinants of nucleic acids may comprise individual bases or base sequences, as in denatured DNA, or specific conformational features, as in helical forms¹. Experimentally induced antibodies have shown selective reactivity toward double-stranded RNA^{2–6}, RNA-DNA hybrids⁴, or distinct features of poly(G)·poly(C)⁷ or poly(dG)·poly(dC)⁴. Some of these antibodies can be used to identify double-helical RNA in virus-infected cells^{8,9} and to quantitate it in RNA extracted from such cells¹⁰, or to distinguish between double-stranded RNA and RNA-DNA hybrids in mixtures of enzyme reaction products¹¹. Triple-helical poly(A)·2poly(U) can also be distinguished from double-helical forms^{2,9}. Triple-helical regions can form where continuous purine sequences occur¹², and they might be involved as intermediates or as recognition sites in transcription^{13,14}. Thus antibodies that recognise triple-helical nucleic acids are important in the definition of conformation-dependent antigenic determinants, as a model for protein recognition of specific nucleic acid sites, and they may identify such sites in naturally occurring nucleic acids. We describe here such antibodies that can differentiate three-stranded structures built on poly(A) from others built on poly(dA).

Sera were obtained from rabbits immunised with methylated bovine serum albumin complexes¹⁵ of copolymers formed by mixing: poly(A)+2poly(U), or poly(dA)+poly(U) or poly(dA)+poly(dT)+poly(U). The sera were tested with single, double and triple-stranded polynucleotides. Sera that reacted with free poly(A) or denatured DNA were passed through columns of DNA bound to Sepharose¹⁶. These absorbed sera, and all others used did not react with native or denatured DNA or with poly(A), poly(U), poly(I), poly(C), poly(dA) or with ribosomal or transfer RNA or double-stranded reovirus RNA, poly(I)·poly(C), poly(dA)·poly(dT) or poly(A)·poly(dT).

Since poly(A) and poly(U) may combine to form either a double-stranded or triple-stranded helix^{17,18}, the specificity of the anti-poly(A)·2poly(U) sera for the triple-helical form was tested when homopolymers were mixed in varying proportions. For reaction with these sera, the maximal amount of effective antigen was present when the ratio in the mixture was 2poly(U):1poly(A) (Fig. 1). When equal amounts of homopolymers were mixed, with the double-stranded form predominant, only 5–10% as much reactive antigen was present. The increase in the amount of effective antigen when the poly(U) was increased from 50% to 67% reflected the transition from a double-stranded to a triple-stranded structure^{17,18}, and was the opposite pattern to that

Fig. 1 Specificity of antisera for triple-stranded polymers, measured by formation of reactive antigens in varying mixtures of poly(U) with poly(A) for anti-poly(A)·2poly(U) antiserum (○) and of poly(U) with poly(dA) for anti-poly(dA)·2poly(U) antiserum (●). Homopolymers (Miles) were mixed at concentrations of 1×10^{-5} M nucleotide in 0.14 M NaCl, 0.01 M Tris, pH 7.4, with 5 mM $MgSO_4$ and 1.5 mM $CaCl_2$. Each mixture was diluted and assayed in quantitative micro-complement fixation as described before²³, but in the above Tris-saline buffer, in a total volume of 1.4 ml per reaction mixture. A complement fixation curve was obtained for each polynucleotide mixture. Relative amounts of reactive antigen were calculated from the total polynucleotide required to reach a given point on the complement fixation curve, such as 50% complement fixation in the antibody excess region. Anti-poly(A)·2poly(U) serum was used at a 1/2,000 dilution and anti-poly(dA)·2poly(U) serum at a 1/1,000 dilution. The broken line represents the maximal theoretical value expected if only triple-helical copolymer is formed.

observed when antibodies to a double-stranded form were used with the same mixtures¹. Further, the anti-poly(A)·2poly(U) serum did not react, even at a 1/100 serum dilution, with double-helical poly(I)·poly(C) or reovirus RNA, while it reacted at a 1/5,000 dilution with the homologous poly(A)·2poly(U). Its reaction with homologous antigen was not inhibited by a hundred-fold excess of native DNA, poly(dA)·poly(dT), poly(A)·poly(dT) or poly(I)·poly(C). Thus this serum was specific for the triple-helical polyribonucleotide.

Antisera were obtained from rabbits immunised with a copolymer made by mixing equal amounts of poly(dA) and poly(U). In this case the original serum reacted, at a 1/1,500 dilution with homologous antigen and at a 1/100 dilution with poly(A) and denatured DNA. After it was passed through a DNA-Sepharose column, it no longer reacted with poly(A) or denatured DNA, but was still fully reactive with homologous antigen.

Mixtures of poly(dA) and poly(U) form only a triple-stranded helix¹⁹, so that even if they are mixed in equal amounts, some poly(dA)·2poly(U) and free poly(dA) are formed. This may have been the case with the immunogen, and could explain the separate antibody population that reacted with poly(A) and denatured DNA and was removed by absorption.

When poly(dA) and poly(U) were mixed in varying proportions, the maximum amount of reactive antigen was again

formed when the ratio was 2poly(U):1poly(dA). However, the pattern differed from that seen with the anti-poly(A)·2poly(U) serum, since in this case there was a continuous increase of reactive antigen as poly(U) was added to poly(dA) (Fig. 1) rather than a sudden increase when the poly(U) was increased above 50%. This supports the conclusion that only the triple-stranded structure is formed.

This serum did not react with the double-helical structures listed earlier, and its reaction with homologous antigen was not inhibited by native DNA, poly(dA)·poly(dT), poly(A)·poly(dT) or poly(I)·poly(C).

Antisera to poly(dA)·poly(dT)·poly(U) were also specific for the triple-stranded form reported to occur with this mixture of homopolymers^{19,20}. The sera did not react with the homopolymer components alone or with poly(dA)·poly(dT) or any of the other single or double-stranded polymers listed earlier.

The specificities of these sera were examined further in tests of reciprocal cross-reactivities among the triple-helical polynucleotides. Even at a 1/100 serum dilution, antiserum specific for the exclusively polyribonucleotide copolymer poly(A)·2poly(U) was not cross reactive with poly(dA)·2poly(U) or with poly(dA)·poly(dT)·poly(U); it was effective with homologous antigen at a 1/1,500 serum dilution.

Antisera to the two forms containing poly(dA) were mutually cross-reactive, giving virtually identical complement fixation curves with either antigen (Fig. 2), but neither cross-reacted with the poly(A)-containing triple-helix. The apparent cross-reactivity of poly(dA)·2poly(U) and poly(dA)·poly(dT)·poly(U) was further examined to determine whether when poly(U) was added to poly(dA)·poly(dT), it simply displaced the poly(dT) to form poly(A)·2poly(U). Specific precipitates were formed with anti-poly(dA)·2poly(U) serum and with either of the poly(dA)·2poly(U) or poly(dA)·poly(dT)·poly(U) antigens. The latter precipitate contained all three nucleotides (Fig. 3). Thus the antiserum did precipitate a polymer containing all three components and the two triple-helices must have similar conformations.

The cross-reaction described above indicated that the presence of the poly(dA) controlled the overall configuration of the two similar polymers, while the presence of poly(A) determined the different conformation of the poly(A)·2poly(U). This role of polypurine was tested further by

Fig. 2 Cross-reactions of triple-helical polynucleotides with anti-poly(dA)·2poly(U) antiserum. Quantitative complement fixation reactions of poly(dA)·2poly(U) (○) and poly(dA)·poly(dT)·poly(U) (▲) with a 1/1,000 dilution of serum and the lack of reactivity of poly(A)·2poly(U) (●) with a 1/100 dilution.

Fig. 3 Analysis of precipitates formed with anti-poly (dA)-2poly(U) antiserum and poly(dA)-2poly(U) or poly(dA)-poly(dT)-poly(U). Poly(dA)-2poly(U) was formed by mixing 4.5×10^{-8} mol of poly(dA) nucleotide with 9×10^{-8} mol of poly(U) nucleotide in 0.3 ml containing 0.3 M NaCl, 0.01 M phosphate, pH 7.4. The mixture was heated at 100°C and slowly cooled to room temperature and then to 4°C . Poly(dA)-poly(dT) was prepared in the same way with a mixture of 4×10^{-8} mol of nucleotide for each homopolymer. An identical amount of poly(U) was then added in 0.15 ml of saline-phosphate at 37°C , and the mixture was cooled to 4°C . Anti-poly(dA)-2poly(U) antiserum (1 ml) was added to each of the two polymer mixtures, and these were incubated for 20 h at 4°C . Both precipitates were collected by centrifugation in the cold, drained, washed with 0.5 ml of saline-phosphate, centrifuged again and resuspended in 0.2 ml of water. The suspension was incubated with $5\mu\text{g}$ of pancreatic RNase for 3 h at 42°C and most of the precipitate dissolved. Pancreatic DNase ($10\mu\text{g}$) and venom phosphodiesterase ($50\mu\text{g}$) were added and the mixtures were incubated for a further 2.5 h at 37°C . The mixture was lyophilised and redissolved in 0.025 ml of water. Of this, 0.01 ml was spotted on an Eastman thin-layer chromatogram with a fluorescent indicator background, and chromatographed in a propanol-ammonium sulphate-phosphate solvent system²⁴. Nucleotides were localised under ultraviolet light, and deoxyribose was localised by a cysteine-sulphuric acid spray²⁵, in comparison with known nucleotide standards that were run in parallel with the hydrolysate. Sample 1 was the hydrolysed precipitate formed with poly(dA)-2poly(U) and sample 2 that formed with poly(dA)-poly(dT)-poly(U). The hatched areas indicate the presence of both ultraviolet-detectable and acid cysteine-reactive material. Most of the latter was in the position of dAMP or, in sample 2, of dTMP as well. Some remained at the origin; in control experiments, protein stained in this way and stayed at the origin.

adding poly(U) to the hybrid poly(A)·poly(dT), which did not react alone with antibody to triple-stranded poly(A)·2poly(U). As poly(U) was added, new complexes formed and reacted strongly with the serum (Fig. 4a). At the same time, the formation of the new complexes was reflected in a reduction in double-stranded antigen available to react with specific anti-hybrid antibody (Fig. 4b). If the third strand were situated in the major groove of the original double helix, as with poly(A)·2poly(U)²¹, it may sterically block some of the double-stranded determinants while forming the triple helix. Alternatively, the addition of the third strand may have altered the conformation of the original double helix. In either case, the effect was not total, as 20–30% of the poly(A)·poly(dT) determinants remained accessible to the anti-hybrid antibodies, as judged from the degree of lateral shift in the complement fixation curve (Fig. 4).

The new complexes of poly(A)·poly(dT)·poly(U) did not react with antisera to either of the poly(dA)-containing helices. Thus the two triple-helical polynucleotides formed with poly(A) were immunologically similar to each other but distinct from the triple-helical polymers formed with poly(dA), while the latter two were very similar to each other.

The structure of the antigenic determinants cannot be defined precisely, but the backbones of two or three strands probably contribute to one determinant, and they must be in the proper orientation with respect to each other, because antibodies reactive with poly(dA)·poly(dT)·poly(U) did not react with poly(dA)·poly(dT) or poly(A)·poly(dT)·poly(U). Similarly, antibodies to double-helical poly(A)·poly(dT) may fail to react with other helices containing one of these chains, such as poly(A)·poly(U) or poly(dA)·poly(dT). Again it seems that portions of both helices, in proper orientation, form one determinant. With several antigen systems, the maximal size of the corresponding antibody combining site is about $7 \times 12 \times 35\text{\AA}$ (ref. 22). This could encompass a full helical turn or the full width of the

Fig. 4 Complement fixation cross reactivity of poly(A)-2poly(U) and poly(A)-poly(dT)-poly(U) with: (a) anti-poly(A)-2poly(U) antiserum and (b) anti-poly(A)-poly(dT) antiserum. The poly(A)-2poly(U) (●) was prepared by mixing 1 volume of poly(A) with 2 volumes of poly(U), with both polymers at a concentration of 0.4×10^{-7} mol of nucleotide per ml in 0.15 M NaCl, 0.01 M phosphate, pH 7.4, at 37°C . Triple-helical complexes (X) were formed by the addition of 1.2×10^{-8} mol of poly(U) nucleotide to 1.6×10^{-8} mol of poly(A)-poly(dT) (△) nucleotide, in 0.025 ml, in 0.4 M NaCl; the mixture was incubated with complement fixation buffer. The anti-poly(A)-2poly(U) antiserum was used at 1/1,000 dilution for reaction with triple-stranded forms and at 1/100 was not reactive with poly(A)-poly(dT). The anti-poly(A)-poly(dT) antiserum was used at 1/1,000 dilution.

helix, including portions of three adjacent strands, in a shallow cavity or groove on the antibody molecule.

Fig. 1 Anti-sheep RBC response in chickens treated with CoF. Plot of haemagglutinin levels (\log_2 titre) following an intravenous injection of 10^{10} sheep erythrocytes. ●—● The average haemagglutinin titres for a group of 10 normal birds. The response reaches maximum at 6 d and thereafter rapidly declines, remaining at or near zero after 16 d. —○—○ Haemagglutinin titres of individual birds treated with cobra venom factor (CoF). The first haemagglutinin response of all birds is slightly increased in comparison with controls at the peak and delayed in the decline phase; all birds also show a further peak (maximum at day 24-25). In the case of one bird a further (third) peak developed (maximum at day 38).

antibody product and is thought to operate by the process of segregation of B cells into germinal centres².

We have investigated the O-agglutinin response to an intravenous injection of 10^9 heated *Salmonella adelaide* O organisms (Fig. 2). The agglutinin response kinetically resembles that to HSA or sheep erythrocytes, but the initial peak and decline is followed by at least four further peaks of declining magnitude. The class of immunoglobulin involved was investigated by treatment of serum samples with 0.3 M 2-mercaptoethanol for 1 h; the results showed that all agglutinin titres were reduced near to zero. Thus, most antibody was 19S immunoglobulin. The occurrence of 7S chicken agglutinins for *S. adelaide* O antigen was further investigated by use of radiolabelled antibodies prepared against chicken 7S and 19S immunoglobulin. Such antisera, shown to be specific for H chains by standard immunoelectrophoresis, were added to washed agglutinates of *S. adelaide* (heated O organisms) prepared in antigen excess, with 25 μ l of neat chicken serum. After 30 min interaction the uncombined radiolabelled immunoglobulin was removed by washing in physiological (0.15 M) NaCl, and the radioactivity remaining attached to the agglutinates was counted. The counts expressing amounts of 19S antibody are shown in Fig. 3 (range of four peak levels 40,000-82,000 c.p.m.). While estimates of antibody of 19S Ig class in serum samples reproduced the pattern of the previously described agglutination tests, counts of absorbed anti-7S Ig were low (range 100-2,000 c.p.m.) confirming the virtual absence of 7S antibody.

The difference between the curve of agglutinins of the serum response to *S. adelaide* O antigen and the antibody responses to HSA and sheep erythrocytes, is attributed to deficient 7S antibody production in the bird in response to an immunogenic stimulus to the lipopolysaccharide O antigen (see also data from the mouse³). It is hypothesised that normal negative feedback of the primary response requires switch over from 19S to 7S immunoglobulin, without which a single injection of antigen causes a series of cyclical fluctuations in 19S antibody.

Antibody responses to bacterial polysaccharides are unique in several ways. Thus, they depend exclusively on the B-cell

Effect of host decompensation on homeostasis of antibody production in fowl

THE primary response to human serum albumin (HSA) in the 6 to 10-week-old fowl is characterised by an early and accelerating rise in antibody level to a peak at about 9 d followed by an abrupt decline¹. Comparison of the kinetics of this decline from the peak gave a close correspondence between it and the curve of decline of passively transfused labelled homologous 7S immunoglobulin. It seems clear that antibody production has been switched off before the peak and little ensues thereafter. The primary haemagglutinin response to sheep erythrocytes has a similar shape but the peak is earlier (Fig. 1)². The *in vivo* suppressive effect is attributed to the negative feedback inhibition of the 7S

system⁴. Lipopolysaccharide O antigens interact with complement and activate the bypass mechanism of the complement cascade⁵.

This leads to the postulate that the switch over from 19S to 7S biosynthesis of antibody may be a complement-dependent process which is selectively inactivated by lipopolysaccharide antigens. Experiments were undertaken in birds which were immunised with a normal immunogenic stimulus (sheep erythrocytes) during a period of treatment with cobra venom factor sufficient to reduce *in vivo* levels of complement. Cobra venom factor (CoF) was prepared by a modification of previous methods^{6,7}.

One unit of anticomplementary activity was taken as the amount required to reduce the haemolytic capacity of chicken serum by 50%. The preparation of CoF reduced complement levels in the above test 160 fold. It was injected (150 U kg^{-1}) every other day according to the schedule recommended in ref. 8.

The response to a single injection of 10^{10} sheep erythrocytes now took the form shown in Fig. 1. The peak of the first rise of serum agglutinins is elevated (from average titre of 2^{10} to 2^{12-13}). The decline phase is somewhat shifted to the right and in all three cases there is a second rise and fall of serum agglutinins which reaches a peak on day 24 at 2^{7-9} titre. In the case of one bird this cycle is repeated once more, the titre reaching 2^7 on day 38. Another consequence was that virtually all antibody was in the form of 19S immunoglobulin without 7S immunoglobulin. The treatment of sera with 0.3 M 2-mercaptoethanol always reduced to near zero the agglutination titre of serum samples of the three treated with CoF shown in Fig. 1. In control birds, agglutinin titres in the period 5–15 d were also considerably reduced by 0.3 M 2-mercaptoethanol. All the reduced sera were treated to determine the presence or absence of incomplete haemagglutinins by addition of rabbit anti-chicken 7S immunoglobulin. In control birds this caused an increase of the peak titre from 2^7 to 2^{10} , the level declining thereafter. The sera of CoF-treated birds failed to show any appreciable increase following addition of rabbit anti-chicken 7S immunoglobulin.

Treatment with CoF, therefore, acts to impede the normal homeostatic mechanisms which terminate the antibody response to sheep erythrocytes. As this effect was accompanied by a defect of the normal switch from 19S to the 7S immunoglobulin form of antibody, an analogy can be drawn with the situation obtaining in the bird's response to *S. adelaide* O organisms. Here, too, the switch from 19S to 7S antibody fails to occur, and presumably this relates to some distinctive property of this type of antigen. Similarly, it was found that the antibody response to the H antigen of *S. adelaide* failed to terminate after the first peak of antibody (at 5–7 d) but underwent repeated cycles of antibody production of slowly diminishing magnitude.

Pepys^{9,10} has found that treatment of the mouse with CoF results in decrease and/or delay in the antibody responses to two thymus-dependent antigens (sheep erythrocytes and alum-precipitated ovalbumin) but no change in the responses

to two other thymus-independent antigens (pneumococcal polysaccharide type III and polyvinyl pyrrolidone). According to Pepys, the possibility that the CoF effect is due to antigenic competition is unlikely as the use of CoF in previous recipients of CoF cancelled the effect—circumstances in which antigenic competition would have been augmented. It was proposed that complement plays a role in T and B cell cooperation.

Our results can be interpreted as a conversion by CoF of the normal response of a thymus-dependent antigen (sheep erythrocytes) into one with the characteristics typical of a thymus-independent antigen. Both the O (lipopolysaccharide) and H (flagellar) antigens of *S. adelaide* are typical thymus-independent antigens^{11–13} in other animals.

A possible hypothesis to account for our present findings is that lipopolysaccharide and other thymus-independent antigens fail to switch 19S to 7S antibody production and fail to secure lasting homeostasis of the response since they activate the alternative pathway and lead to $\text{C3} \rightarrow \text{C3b} \rightarrow \text{C3b}$ (inactive) conversion⁹.

Fig. 3. Plot of antibody levels estimated by radio-immunoassay for individual birds injected with 10^9 *S. adelaide* O organisms. The response consists of a regular series of separated peaks, each followed by a phase of decline. At least five peaks are recognisable for each bird. Each plot represents the response of one bird.

Finally, it becomes necessary to investigate whether a T-independent response owes its characteristics (recycling of antibody production and lack of 7S response) to a positive anticomplementary action which causes an ineffective switch from 19S to 7S antibody production and defective homeostasis secondarily to a lack of avid 7S antibody. The consequences of this hypothesis can readily be tested and we hope to report the results of such investigations at a later date.

Vaccinia virus cytotoxin(s)

THE mechanisms whereby cytopathic viruses damage or kill susceptible cells are not fully understood. Some experiments with pox viruses involving partially inactivated virus or various metabolic inhibitors suggest a correlation between the production of virus proteins and the appearance of cytopathic effects without necessarily establishing a casual relationship between the two events^{1,2}. Other work suggests that inhibition of host protein synthesis, and by extension induction of cytopathic effects by vaccinia virus, is independent of virus-induced protein synthesis but is some function of the virus particle itself³. Here, we report direct experiments in which vaccinia-specific materials were isolated from infected HeLa cells, rendered free from infective virus and shown to be toxic to susceptible uninfected HeLa cells under appropriate test conditions. To our knowledge this is the first documented example of an observable cell-killing effect of vaccinia specific protein(s). It differs from that of the penton capsomere (toxin) of adenovirus which affects cell membranes from the outside causing them to detach from glass⁴, in that we believe it acts intracellularly.

HeLa cells were infected with vaccinia virus and collected 48 h after infection; soluble virus-free preparations (HVSA) containing both viral and hostspecific precipitinogens were prepared⁵. Preliminary work confirmed previous observations^{1,6} that HVSA had no effect on its own when added to cultures of HeLa cells either in suspension or in monolayers. This meant that either no virus-induced toxic substances existed, or, that they did and were not being taken up by the cells. To test the latter possibility a suitable biological system was sought in which cells could be induced to take up macromolecules in a biologically active state. Various membrane modifiers or uptake inducers⁷⁻¹¹, were tried but none proved more effective or easy to handle than hypertonic salt solutions.

For the test system, HeLa cells were assigned to four groups: group 1 was treated with calf serum medium, group 2 with calf serum medium and MgSO₄ (at the maximum concentration which resulted in $\geq 95\%$ cell survival; see Fig. 1a), group 3 with uninfected cell extract and MgSO₄ and, group 4 with HVSA and MgSO₄. Several hours after treatment, some of the HVSA-treated cells were dead as judged by vital staining; after overnight incubation when dead cells had detached and disintegrated, viable cells were stained and counted. The results of 23 experiments (Fig. 1b) show that there is in HVSA, something which is lethal to approximately 30% of HeLa cells present in the test population.

To determine the specificity of this cytotoxic mechanism HVSA was fractionated, using -S-S- linked immunosorbents^{12,13} derived from sera⁹ raised to uninfected HeLa cells or sera from rabbits infected with rabbit-grown vaccinia virus, to yield HeLa- and vaccinia-specific fractions, each overtly uncontaminated by the other in immunodiffusion tests. HVSA was also fractionated on DEAE-cellulose to yield a toxic fraction (Fig. 2) which contained several demonstrable vaccinia antigens in immunodiffusion tests. Only vaccinia-specific fractions were toxic; uninfected cell

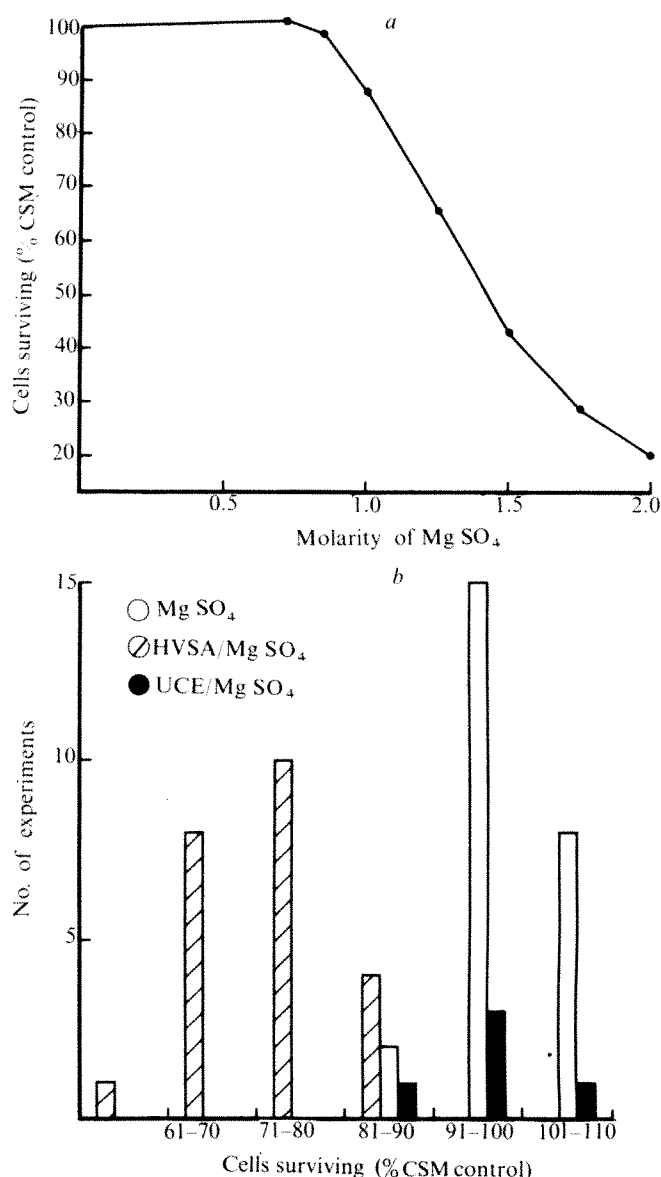

Fig. 1 Survival of HeLa cells treated with MgSO₄, infected cell extract (HVSA)/MgSO₄ and uninfected cell extract (UCE)/MgSO₄, expressed as a percentage of a calf serum medium (CSM)-treated control. Cells from 4 to 6-d-old monolayers were collected with EDTA, counted, diluted in CSM and continuously stirred. Samples (0.2 ml) were pipetted into the wells of a microtitre plate (Flow, M29-ART) so as to give 300-400 cells per well, and the plates centrifuged at 150g for 10 min. Plates were incubated overnight (37°C, 5% CO₂ in air). CSM was removed by inverting the plate, subjecting it to a sharp wrist flick, and removing the residual fluid by placing the plate on sterile filter paper. The cells were treated as follows: *a*, Varying concentrations of MgSO₄ in CSM were added and the cells subjected to the manipulative/counting procedures described in *b*. The object was to determine the highest concentration of MgSO₄ which $\geq 95\%$ of the cells would tolerate, that is, cells would go on to divide upon being returned to CSM. In this case it was 0.85 M MgSO₄, and this was used in the test as described below. Every line (or subline) of HeLa cells used was examined for MgSO₄ sensitivity. This only varied significantly when HeLa cells of a different source or cells obtained by certain selection pressures are used. When one line of normal cells is used the variation from day to day was minimal. *b*, For the test, the following mixtures were added: 0.85 M MgSO₄ in CSM, HVSA (or UCE) mixed with an equal volume of 1.7 M MgSO₄ in CSM, or CSM alone as a control. The cells were treated for 15 min at 37°C, washed twice in 0.2 ml volumes of CSM by the method described above and incubated in 0.2 ml of CSM overnight. Twenty-four hours after treatment the cells were

washed in phosphate buffer (PBS, pH 7.0, I , 0.26), stained for 15 min in freshly filtered 1% crystal violet in PBS Dulbecco A, washed in PBS, stained for 5 min in Lugol's iodine, and washed in PBS again. The wells were filled with PBS and covered with a piece of glass to avoid a refracting meniscus and the cells were observed using the $\times 4$ objective of a Prior Inverted microscope. Cells in the four corners of each well were counted representing about 80% of the area of the well; counts of about 500 cells per well were obtained with a standard deviation of 36 for CSM-treated controls. Routinely 8 or 12 wells were used for the CSM or $MgSO_4$ controls and four wells (to conserve materials) for the HVSA and UCE samples. The majority of tests resulted in approximately 70% of the cells surviving the combined $MgSO_4$ +HVSA treatment, where the control for $MgSO_4$ -treated cells was $99 \pm 6\%$ of the CSM control. Histogram shows data from 23 such experiments involving HSVA survival, in brackets of 10%, the frequency with which a given survival of cells was observed. The data for $MgSO_4$ only treatment is derived from the same experiments and is given to show the mildness of this treatment. A similar spread of results for CSM treated cells is obtained when these are measured as a percentage of the $MgSO_4$ -treated control.

Fig. 2 Titration of toxicity of crude HVSA and partially purified vaccinia-specific antigens. HVSA (1.0 ml) was adsorbed to DEAE-cellulose (phosphate buffer pH 6.8, I , 0.0175) and eluted with stepwise increments of NaCl. The only toxic fraction (DE-V) was that eluted by 1.0 M NaCl and this was concentrated to 1.0 ml and titrated. Titres were expressed as the highest dilution causing death of the maximum number of susceptible cells in the system. Representative results are shown above. Initial concentrations of protein for HVSA □, and DE-V ●, were 20 and 2 mg ml⁻¹ respectively, representing a 10-fold purification. The total toxic activity expressed by DE-V was thus eight times greater than that of crude HSVA per unit volume and 80 times greater per mg protein.

extracts and HeLa materials from infected cells were not toxic in this test. The possibility that some virus-specific component allowed the cells to take up a toxic dose of $MgSO_4$ during the (technically convenient) simultaneous exposure of cells to $MgSO_4$ and HVSA (or vaccinia-specific fractions) was examined by pretreating cells with $MgSO_4$, removing $MgSO_4$, and adding HVSA; the latter still exhibited toxicity, thereby eliminating this possibility. The only biochemical activity associated with HVSA that we have demonstrated so far is the ability to release lysosomal enzymes¹⁴ from rabbit liver lysosome preparations. The level of pre-released β -glucuronidase (the marker enzyme chosen for assay) in uninfected cell extract was twice that in HVSA (due presumably to the loss of enzymes into the medium from the necrotic cells from which HVSA is prepared), but only HVSA caused the release of more enzyme (20–70% of maximum releasable by Triton-X100) from intact lysosomes.

Attempts to titrate toxicity showed that the activities of neat HVSA and 1/2 dilutions of HVSA were approximately the same as judged by the number of cells killed (approximately 30% in each case) and at higher dilutions the activity dropped rapidly to zero. This seemingly low activity may reflect the presence of inhibitors in HSVA. For example, comparative titration of HVSA (20 mg protein ml⁻¹) and the DEAE-cellulose toxic fraction (2 mg protein ml⁻¹) showed the latter to be eight times more active per unit volume or 80-fold more active per mg protein (Fig. 2). All these estimates of toxicity are conservative because activity dropped rapidly to zero. This seemingly low activity apparently stores indefinitely at -20° or -70° C, was slowly inactivated at 37° C, but in the presence of 0.85 M $MgSO_4$, all toxic activity was abolished after 15 min incubation at 37° C.

Preliminary experiments have been carried out in which HVSA was treated with a solid-phase protease (trypsin linked to Enzacyl AA, Koch-Light). This resulted in a loss of toxicity which, together with the fact that immunosorbents specific for vaccinia antigens removed the toxicity from HVSA, suggests that the active factor(s) is a protein and not infectious nuclei acid¹⁵ or double-stranded RNA¹⁶.

Various approaches have been tried, with crude HVSA, to discover why only 30% of the cells were killed. Presumably there is a subpopulation of HeLa cells with the ability to take up and/or be killed by the toxic factor(s) present in HVSA, an attribute which could be dependent on either

phenotypic or genotypic heterogeneity. First, synchronous cultures of HeLa cells were prepared by mitotic selection and hydroxyurea treatment¹⁷ and used in the test system at four different time points spanning one growth cycle. No difference was detected in the susceptibility of cells to HVSA with respect to different phases of cell growth; in each case only 30% of the cells died. Second, attempts were made to select cells which exhibited a more uniform response to $MgSO_4$ stress when the latter is applied to cells in monolayers. This would be reflected in a steeper drop in the viability of cells beyond some critical concentration of $MgSO_4$. To date we have not succeeded in selecting a population possessing this kind of sensitivity as a stable characteristic. The third experiment was carried out with cells derived from the survivors of a toxicity test and again only 30% of the cells died. It is technically very difficult to carry out a quantitative test on the survivors. These experiments suggest that susceptibility to the cytotoxic factor depends on a hitherto undefined transient physiological state which allows some of the cells, on treatment with $MgSO_4$, to take up a lethal dose of cytotoxin.

In summary, we present evidence for the existence of vaccinia-specific protein(s) which under defined conditions can cause the death of susceptible HeLa cells. Formal proof that the toxic action is an intracellular as opposed to a membrane-mediated one is difficult to obtain. But no toxicity is induced by HSVA *per se* in contrast to, for example, adenovirus penton which interacts with cell membranes causing them to detach from glass surfaces⁴.

Finally we would not extrapolate from these results to suggest that pox-virus infections are accompanied by a toxæmia in the classical bacterial sense—no such evidence has ever been adduced—but we think that an examination of virus-specific products isolable from infected animal tissues would be worthwhile. This might lead to the recognition of virus-induced factors, which are toxic to the cells in which they are made, and which contribute to the overall complex mechanism of viral pathogenicity.

This work was carried out with the support of the Pro-

curement Executive of the Ministry of Defence.

Effects of dopamine-like drugs on rat striatal adenylyl cyclase have implications for CNS dopamine receptor topography

THE involvement of central dopaminergic neurones in the pathogenesis of several extrapyramidal movement disorders is well documented^{1,2}. Moreover it has been suggested that dopaminergic mechanisms may also be involved in the physiological mechanisms underlying psychoses³. For these reasons there is considerable neuropharmacological interest in the interaction between anti-Parkinsonian and neuroleptic drugs and central dopaminergic systems. Recently it has been shown that homogenates of tissues containing dopaminergic synapses respond to low concentrations of dopamine by an increased production of cyclic AMP. These areas include the bovine superior cervical ganglion⁴, the rat and bovine retina⁵, rat basal ganglia⁶, olfactory tubercle, nucleus accumbens⁷ and cortex⁸. The effects of dopamine in some of these systems are mimicked by dopamine receptor stimulating drugs such as apomorphine^{6,7} and 1-(3,4-dihydroxybenzyl)-4-(2-pyrimidyl) piperazine (S584)⁹ and antagonised by neuroleptic drugs^{6,10-12}. It seems, therefore, that these systems represent valid models of CNS dopamine receptors and it has been suggested that they may even comprise the dopamine receptor itself⁶. We have studied the dopamine-sensitive adenylyl cyclase of the rat striatum in order to define some of the structural requirements for dopamine receptor agonists.

In accordance with previous reports¹⁰, we found that addition of low concentrations of dopamine to rat striatal homogenates increased cyclic AMP accumulation during a

brief incubation *in vitro*. Half maximal stimulation was obtained at approximately 3 μ M dopamine. Experimental details are shown in Fig. 1. The effects of various compounds related to dopamine and apomorphine were also investigated. Homogenates were incubated with drugs at concentrations between 10⁻⁶ and 10⁻³ M. These results are summarised in Tables 1 and 2.

Dopamine and its N-methyl derivative epinine had similar activities as agonists. Further methyl group substitution of the amine function as in the N,N-dimethyl and the quaternary methyl dopamine derivatives led to compounds that were less active agonists.

Fig. 1 Effect of cyclic analogues of dopamine on stimulation of cyclic AMP production in rat striatal homogenates. Sprague-Dawley rats weighing 180-250 g were used. The rats were decapitated and their brains rapidly removed and placed on ice. The striata were dissected as in ref. 25 and homogenised with a motor driven teflon/glass homogeniser in approximately 25 vol (w/v) of 2 mM Tris maleate buffer pH 7.4 containing 2 mM EGTA. Fifty microlitre aliquots of this homogenate were added to 250 μ l of 80 mM Tris maleate buffer, containing 2 mM MgSO₄, 0.2 mM EGTA and various drugs as indicated. The incubation tubes were kept on an ice/salt bath while ATP was added to a final concentration of 0.5 mM. The incubation tubes were then placed in a shaking water bath at 30°C for 2.5 min. At the end of this time the tubes were transferred to a boiling water bath for 2.5 min. The contents of each tube were centrifuged for 5 min in a microcentrifuge to sediment the denatured protein. 10 μ l aliquots of the supernatant were assayed for cyclic AMP content by the method of Brown *et al.*²⁶ using a linear standard curve produced with aliquots of authentic cyclic AMP between 0.2 and 8.0 pmol. The levels of cyclic AMP increased from a basal level of 31.8 \pm 0.96 pmol per assay tube (approximately 2 mg wet weight tissue) to 66.9 \pm 3.69 pmol per assay tube (mean value \pm s.e.m. $n=9$) in the presence of a maximally stimulating concentration of dopamine (100 μ M). Incubations with dopamine at 100 μ M was included in every experiment for comparison. As the stimulation produced by 100 μ M was slightly variable between experiments the effect of each agonist was compared with the effect of 100 μ M dopamine in the same experiment using the same striatal homogenate. The effect of 100 μ M dopamine was normalised to 100%. Results are means of between four and 10 separate incubations, standard errors were less than \pm 10%. Numbers on graphs refer to the structures given in Tables 1 and 2.

* Stimulation produced by 100 μ M dopamine is taken as 100%. For experimental details see Fig. 1.

† EC50 refers to concentration required to give half maximal stimulation produced between 10⁻⁶ and 10⁻³M. Agents shown as giving no stimulation of cyclic AMP production were not significantly effective ($P > 0.05$) at concentrations between 10⁻⁶ and 10⁻³M.

‡ Incubations included 0.4 mg ml⁻¹ of the dopa decarboxylase inhibitor NSD 1055 control incubations showed this had no effect on basal or dopamine-stimulated cyclic AMP production.

Compounds having 1–4 carbon atoms between the catechol nucleus and the primary amino group were examined. It was found that only dopamine, which has a 2 carbon side chain, was active. The analogues containing 1, 3 or 4 carbon atoms in the chain were all inactive. Incorporation of the side chain into a second ring system in an extended form as in 2-amino-6,7-dihydroxy-1,2,3,4-tetrahydronaphthalene and apomorphine produced active agonists, whereas when the side chain was incorporated in a ring system in its nonextended form as in 6,7-dihydroxy-tetrahydroisoquinoline the resulting compound was much less active than the corresponding β -naphthylamine (Fig. 1). Substitution of a methyl group in the 1 position of the latter compound in salsolinol led to an inactive compound. Substitution of even larger groups at the 1 position also produced inactive compounds such as tetrahydropaveroline and the emetic drug emetine.

Compounds lacking the catechol group were inactive. Thus the *m* and *p* isomers of tyramine, *m* and *p*-methoxydopamine, amphetamine, apomorphine, dimethoxy-apomorphine and 2-amino-1,2,3,4-tetrahydronaphthalene did not stimulate the adenyl cyclase. Apomorphine, *dl*- α -methyl-dopamine and in particular 2-amino-6,7-dihydroxy 1,2,3,4-tetrahydronaphthalene, were all active in stimulating the enzyme system.

dl- α -Methyldopamine was less active than the parent compound. *l*-Noradrenaline was less than half as active as dopamine at a concentration of 1 × 10⁻⁵ M. The *d*-isomer of noradrenaline was inactive in concentrations up to 10⁻³ M. L-dopa was totally inactive.

As 2-amino-6,7-dihydroxy-1,2,3,4-tetrahydronaphthalene was such a potent agonist, the effect of neuroleptic drugs on its adenyl cyclase stimulating ability was examined. The clinically efficacious neuroleptic chlorpromazine (1 × 10⁻⁶ M) potently inhibited the stimulation of the

enzyme system by this agonist, whereas promethazine 1 × 10⁻⁶ M, which is a phenothiazine antihistamine with little or no neuroleptic activity¹³ was much less active (Fig. 2). Similar results have already been reported for dopamine⁷. In addition a maximally stimulating concentration of dopamine (100 μ M) did not increase the stimulation produced by 100 μ M 2-amino-6,7-dihydroxy-1,2,3,4-tetrahydronaphthalene. These observations suggest that the two agonists have the same locus of action.

It is of interest that in two other dopamine-sensitive preparations, namely the renal artery of the dog¹⁴ and certain neurones of the snail *Helix aspersa*¹⁵, epinine was also found to be equipotent with dopamine. Among the simple dopamine analogues there is an absolute requirement for a catechol grouping and a 2 carbon side chain attached to an amino group. The structural and conformational requirements of the amino group are apparently less stringent, as even the quaternary methyl ammonium compound still retains some activity. Activity is also not abolished when the amino group is incorporated into a second ring as in 6,7-dihydroxy-tetrahydroisoquinoline. Due to the greater potency of the dopamine analogues where the side chain is incorporated in an extended form, as in 2-amino-6,7-dihydroxy-1,2,3,4-tetrahydronaphthalene and apomorphine, it seems that the preferred conformation of dopamine on interaction with the adenyl cyclase system is probably similar to the fully extended *trans* form. This has been shown to be the preferred conformation of dopamine in the solid state by X-ray crystallography¹⁶, in solution by NMR analysis and *in vacuo* by theoretical calculations¹⁷. Calculations based on published X-ray data for dopamine¹⁸ and apomorphine¹⁹ of the interatomic distance between the catechol oxygens O₁ and O₂ and the nitrogen atom of the amino group show that in dopamine N–O₁ is 6.83 Å, and N–O₂ is 7.83 Å. In the two *gauche* forms of dopamine

* Stimulation produced by 100 μ M dopamine is taken as 100%. For experimental details see Fig. 1.

† EC50 is taken as the concentration giving half maximal stimulation obtained between 10^{-3} and 10^{-6} M.

Fig. 2 Effect of *b*, 10^{-6} M chlorpromazine and *c*, 10^{-6} M promethazine on a maximally stimulating concentration of 2-amino-6,7-dihydroxy-1,2,3,4-tetrahydronaphthalene (10^{-4} M). *a*, 10^{-4} M 2-amino-6,7-dihydroxy-1,2,3,4-tetrahydronaphthalene alone. Basal cyclic AMP levels for experiments in Fig. 2 were 32.5 pmol per assay tube (2 mg wet weight of tissue). For experimental details see Fig. 1.

(Fig. 3) these interatomic distances are significantly smaller¹⁹. This may be regarded as further evidence for the concept that the preferred active-site conformation of dopamine resembles the fully extended *trans* form. Molecular models of the rigid analogue 2-amino-6,7-dihydroxy-1,2,3,4-tetrahydronaphthalene clearly show that the conformation of the amino and catechol group is very similar to that occurring in the crystal structure of dopamine, thus probably accounting for its potency as an agonist. Similar suggestions have been advanced by Rekker *et al.*¹⁹ who have argued against Kier and Truitt's²⁰ suggestion that the *gauche* conformation of dopamine, and hence the tetrahydroisoquinoline portion of apomorphine, are the im-

Fig. 3 *a-c*, Newman projections of dopamine conformers: *a*, *trans*; *b*, *c*, *gauche*; *d*, apomorphine.

portant conformations and moieties, respectively, for interaction with the dopamine receptor. The conclusions of Rekker *et al.* are supported by our present results. These findings also support the suggestion of Horn and Snyder²¹ that the preferred conformation of dopamine at its receptor site is similar to the fully extended *trans* form, and that this conformation could be superimposed on the X-ray structure of chlorpromazine, hence accounting possibly for the receptor blocking activity of the latter compound.

The results reported here may help in the design of future dopamine receptor stimulating agents. In particular rigid analogues of dopamine such as 2-amino-6,7-dihydroxy-1,2,3,4-tetrahydronaphthalene or other similar compounds may be useful anti-Parkinsonian drugs^{22,23}. Initial studies suggest that 2-amino-6,7-dihydroxy-1,2,3,4-tetrahydronaphthalene does not cross the blood brain barrier and possibly modifications of the molecule to increase its lipid solubility should be examined.

We gratefully acknowledge the receipts of drugs from Professor M. Sandler, Professor T. Sourkes and J. Fry. R.M. is the holder of an MRC research scholarship. We thank Drs. M. L. Post and O. Kennard, of the University Chemical Laboratory, for providing computer calculated interatomic distances.

Demonstration of indolaminergic fibres in the median eminence of the duck, rat and monkey

MANY reports provide physiological evidence that monoaminergic (catecholaminergic and serotonergic) systems are involved in the control of the secretion of the hypothalamic hormones (releasing factors) at the level of the median eminence (ME) of the rat^{1–3}. Dopaminergic and noradrenergic fibres have been shown in the median eminence by histofluorescence technique^{4–7}. This technique fails to demonstrate the serotonin (5-HT) fluorophores because of their low yield and rapid fading⁸.

As serotonergic neurones are able to take up and retain selectively endogenous or exogenous 5-HT, we have used ³H-5-HT to demonstrate by radioautography⁹ serotonergic, or more generally, indolaminergic neurones in the ME of three species; the duck (Pekin), the rat (Wistar) and the macaque (*Macaca mulatta*). Adult male ducks and rats and adult female monkeys were used as experimental animals. They were all pretreated with a monoamine oxidase inhibitor (nialmide) injected intraperitoneally at the rate of 200 mg kg⁻¹ for 4 h before administration of the tracer which was given either *in vivo* by intraventricular^{6,10} injection, or *in vitro* by incubation.

In the *in vivo* experiments, the animals were killed 30 min to 3 h after tracer administration. The animals were perfused with saline, then with 3.64% glutaraldehyde solution in 0.05 M phosphate buffer. The dissected tissues were postfixed in 2% OsO₄ in the same buffer, dehydrated in ethanol and embedded in Epon. For *in vitro* experiments, the following procedure was used. After decapitation, the median eminence was incubated in 5 ml of a physiological medium containing 0.2 μCi ml⁻¹ and 0.02 μg ml⁻¹ of ³H-5-HT, that is a 10⁻⁷ M concentration of ³H-5-HT. This low concentration was maintained by a continuous renewal of the incubation liquid. The incubation lasted 45 min at 37° C (ref. 11). The tissues were then rinsed in saline, fixed in glutaraldehyde, and treated for electron microscopy as described above.

In each case, radioautographic treatment was performed as follows: thick sections were placed on glass slides, then coated with K5 (Ilford) emulsion and exposed for 15 d before development in D19B (Kodak). Thin sections were put on celloidin-coated slides, stained with uranyl acetate and lead citrate and coated with a carbon film and a monolayer of L4 (Ilford) emulsion. After exposure for 3–6 weeks, the slides were developed in Microdol X (Kodak). The treated sections were transferred to copper grids and observed in an electron microscope¹².

In the three species, locations of radioautographic reactions after intraventricular injection of the tracer gave results identical to *in vitro* incubation. In the duck, very dense accumulations of silver grains were mainly localised in the most external layers of the ME in the vicinity of hypophysial primary portal vessels (Fig. 1). In the rat, clusters of silver grains were seen throughout the ME and were particularly abundant in the most external layers (Fig. 2a). In the monkey, the radioautographic reaction affected all layers of ME (Fig. 2b). Moreover, dense

Fig. 1 Electron microscope radioautographs of two adjacent thin sections of duck ME after intraventricular injection of ^3H -5-HT. There are dense accumulations of silver grains on reactive fibres while the background is practically free. The comparison of the two pictures shows the labelling of the same fibre in the two sections. This fibre reaches the basement membrane (BM). Insets show *a*, a degenerating fibre in the same region after 5,6-DHT treatment and, *b*, an enlarged, labelled fibre with characteristic 1,000 Å dense granules.

and elongated clumps of silver grains frequently overlaid axonal bundles in the internal region.

In all three cases, electron microscopic examination revealed that labelled structures were axonal varicosities (from 0.3–1 µm) representing less than 1% of axonal sections in the ME. These labelled fibres contained densely packed inclusions: electron lucent vesicles and more scarce but very typical dense granules of larger size (1,000 Å) (Figs. 1 and 2). Some labelled terminals were seen in contact with the basement membrane close to portal vessels which are external and internal in mammals but only external in the duck. Other fibres made contact with a tanyocyte process but no synaptic differentiation could be seen at this level.

Our results give rise to three main questions concerning the nature of the radioactive molecules retained in the tissues, the identity of the labelled fibres and the function of such an innervation.

As the main pathway of catabolism of 5-HT is its oxidation by MAO (ref. 13), which was inhibited in our experiments, it seems probable that observed radioautographic reactions marked mainly the molecules of ^3H -5-HT.

The second question raises the problem of the specific labelling of indolaminergic neurones by ^3H -5-HT, as at high concentrations, 5-HT may be taken up into adrenergic neurones¹⁴. Thus, the most convincing evidence for selective uptake of ^3H -5-HT by 5-HT fibres comes from results of *in*

vitro incubations because at the concentration used (10^{-7} M), ^3H -5-HT is specifically taken up by serotonergic neurones¹⁵. Moreover, the ultrastructural features of the labelled fibres are clearly differentiated from those previously described in noradrenergic fibres^{6,7}. Noradrenergic fibres are larger and contain more scattered inclusions among which eccentric core vesicles appear to be characteristic. On the other hand, dense 1,000 Å granules seemed typical of ^3H -5-HT labelled fibres¹⁶. Finally, the pattern of labelled fibres after the administration of ^3H -5-HT was different from that obtained after administration of labelled catecholamines¹⁶. This fact was particularly clear in the duck ME where catecholaminergic fibres are concentrated in the internal zone.

A complementary pharmacological approach was attempted in this species to confirm the specificity of radioautographic results. Two intraventricular injections of 100 µg of 5,6-dihydroxytryptamine (5,6-DHT) which selectively destroys indolamine neurones^{8,17}, were administered 4 and 2 d before the application of the tracer. After this treatment, no incorporation of ^3H -5-HT was observed in the ME, and degenerating fibres appeared in the external zone (Fig. 1*a*).

All these results demonstrate the existence of indolaminergic fibres in the ME. To assume that they are truly serotonergic it would be necessary to identify them with structures containing 5-HT, the existence of which has been biochemically proved in bovine¹⁸ and duck¹⁹ ME.

Fig. 2 Light microscope radioautographs of the ME of, *a*, the rat after intraventricular injection of ^3H -5-HT and, *b*, of the macaque after low concentration *in vitro* incubation in ^3H -5-HT. Note the localised distribution of radioautographic reaction and the low background. In the rat ME the tracer is preferentially localised near the internal and external plexuses. Insets show labelled fibres in each animal after low concentration *in vitro* incubation in ^3H -5-HT. V, Third ventricle.

In the absence of clearly defined synaptic junctions, we can only speculate on the function of the indolaminergic fibres²⁰. Their proximity to the processes of tanycytes and to external basement membrane indicates that they may be involved in the transport of hypothalamic factors by glial cells and/or their release into the portal vessels.

We thank Professor Droz, Dr A. Findlay and Dr T. K. Bhattacharyya for their helpful criticisms of the manuscript. This work was supported in part by a grant from D.G.R.S.T. (Paris). Nialamide was supplied by Pfizer.

Antibody to bovine choline acetyltransferase and immunofluorescent localisation of the enzyme in neurones

THE neurones of the central nervous system that contain catecholamines, or serotonin, can be visualised histochemically by the highly fluorescent products that they form in the presence of formaldehyde vapour¹. No such elegant method exists for demonstrating the cholinergic neurones. Published methods for the histochemical localisation of cholinergic terminals and choline acetyltransferase (ChAc)^{2–5}, which is considered to be exclusive to them⁶, are indirect and non-specific. Recently, ChAc has been

purified and partially characterised from bovine caudate nuclei⁷. We report here (1) the production of specific precipitating antibody against bovine ChAc in the guinea pig; (2) characterisation of the antibody by immunodiffusion, by immunoelectrophoresis, by electrophoresis of the specific immunoprecipitates and by enzyme analyses, and (3) the visualisation of the cholinergic neurones in the central nervous system by the immunofluorescent method using specific antibody against purified ChAc. The specific antibody to ChAc can now be used in conjunction with the recently improved immunohistological technique⁸ to map the cholinergic pathway in the nervous system and to establish the localisation of the enzyme within the cholinergic neurone and its processes at the cellular level. Using the horse radish peroxidase technique⁹ and specific antibody to the glial fibrillary acidic protein, this astrocyte specific protein has been localised only within fibrous astrocytes and their processes at the light and electron microscopic levels⁹.

Specific precipitating antiserum to purified ChAc⁷ was prepared in albino male guinea pigs (600–700 g) as follows. Each animal received an emulsion containing 225 µg of ChAc, 0.7 ml 0.85% saline and 0.7 ml complete Freund's adjuvant (3.5 mg *Mycobacterium tuberculosis* H37RA) by intradermal injection distributed equally among twelve sites in the back. Seven days later an emulsion containing 125 µg ChAc, 0.7 ml 0.85% saline and 0.7 ml complete Freund's adjuvant was injected into six other sites in the back. Fourteen days after the first injection, an emulsion containing 125 µg ChAc, 0.7 ml of 0.85% saline and 0.7 ml of incomplete Freund's adjuvant was injected into six other sites in the back. Thirty-five days after the first injection, the two guinea pigs were bled by heart puncture.

Immunodiffusion and immunoelectrophoresis studies with the guinea pig antisera were performed as before¹⁰. Both antisera formed specific immunodiffusion lines against the crude extract of caudate nuclei, partially purified ChAc and purified ChAc but did not react against bovine serum or haemoglobin. The preimmunisation guinea pig sera did not react with any of the ChAc-containing extracts, bovine serum or haemoglobin. When the purified enzyme was subjected to immunoelectrophoresis at pH 8.6, one precipitin line was formed which corresponded to the area of migration for the ChAc when purified ChAc or a concentrated solution of crude extract of bovine caudate nuclei were used (Fig. 1).

Precipitates of immunoglobulin-ChAc complexes were prepared for electrophoresis by incubating the ChAc-containing solution with the antiserum for 1 h at 37°C followed by 20 h at 4°C. The precipitates were pelleted by centrifugation at 2,000g for 30 min in the cold and washed twice by resuspension in saline and centrifuged as before. Disc polyacrylamide gel electrophoresis in sodium dodecyl sulphate (SDS) of the crude enzyme extract, purified ChAc and immunoprecipitates were carried out as before^{10,11}.

The homogeneity of ChAc has been demonstrated by polyacrylamide gel electrophoresis at pH 9.5 and 7.3 at different gel concentrations (ref. 7). The enzyme behaved as only one sharp peak in sedimentation velocity studies (L.P.C. and F.W. unpublished results) and also only one peak was obtained on gel filtration (L.P.C. and F.W., submitted for publication). The multiple bands in the SDS-polyacrylamide gel electrophoresis are not contamination but are rather aggregated subunits of the enzyme since ChAc aggregates easily¹². Similar aggregation in SDS-polyacrylamide gel electrophoresis has been found for purified glutamic acid decarboxylase¹³, and this enzyme has been localised successfully in rat cerebellum by the immunohistochemical technique¹⁴.

Electrophoresis at pH 7 in SDS (Fig. 2) of the ChAc (gel 3a) showed a major component migrating in the range

Fig. 1 Immunoelectrophoresis of purified bovine ChAc and crude extract of bovine caudate nuclei. Samples electrophoresed: *a*, ChAc; 3 mg ml⁻¹; *b*, crude extract of caudate nuclei, 17 mg ml⁻¹. Sera in the immunodiffusion troughs: 1, preimmunisation guinea pig serum; 2, serum containing specific antibody to ChAc.

of 60,000–67,000 molecular weight with additional minor components. Gels 2b and 2c are immunoprecipitates obtained by mixing the crude extract with the antiserum, and gels 3b and 3c are precipitates obtained by mixing the purified ChAc with the antiserum. In the absence of Cleland's reagent (reducing agent), the immunoprecipitates from the crude extract (gel 2b) and the purified ChAc (gel 2c) showed intact 160,000 molecular weight immunoglobulin and the ChAc bands. In the presence of Cleland's reagent, the immunoprecipitates from the crude extract (gel 3b) and the purified ChAc (gel 3c) showed the major enzyme band, the 53,000 molecular weight heavy chain, and the 25,000 molecular weight light chain of the dissociated immunoglobulin. The minor enzyme bands were obscured by the heavy chain immunoglobulin. The electrophoretic analyses of the specific immunoprecipitates demonstrate that the antiserum reacts specifically with the purified ChAc with was used to elicit the antibodies in the guinea pig.

Fig. 2 Polyacrylamide gel electrophoresis in sodium dodecyl sulphate of a crude extract of caudate nuclei, purified ChAc, and immunoglobulin-ChAc complexes. Gels 1a–3a contain 7.5% acrylamide. Gels 1b–3b and 1c–3c contain 10% acrylamide. The protein samples in gels 1a–3a and 1c–3c were treated with Cleland's reagent; gels 1b–3b were not treated with Cleland's reagent. Gels 1a, 1b and 1c were mixtures of conalbumin (*a*), serum albumin (*b*), ovalbumin (*c*), chymotrypsinogen A (*d*), and cytochrome (*e*). Gel 2a was the crude extract from caudate nuclei; gel 3a was the purified ChAc; gels 2b and 2c were immunoprecipitates obtained by incubating the crude extract with antiserum, and gels 3b and 3c were immunoprecipitates obtained by incubating the purified ChAc with antiserum.

For enzymatic studies, aliquots of partially purified ChAc (50 μ l) (which is more stable than the purified ChAc)⁷ were incubated with equal amounts of each of the three following solutions: (1) 0.05 M potassium phosphate, pH 7.0, containing 0.5 mM EDTA and 7% glycerol; (2) immunised guinea pig serum; (3) preimmunised guinea pig serum. The incubations were carried out at 37°C for 1 h and then at 4°C for about 20 h. The three mixtures were centrifuged at the end of incubation. The enzymatic activity in the supernatants and their corresponding resuspended precipitates were determined by the spectrophotometric method¹⁵ in the presence of creatinine-HCl¹². No precipitates were formed in the controls (mixture 3, preimmunised serum). White precipitates could be seen in the tubes containing ChAc alone (mixture 1) or ChAc plus immunised serum (mixture 2), however, the precipitates showed no enzyme activity. The enzymatic activity recovery was 88%, 69% and 95% in the supernatants for the ChAc incubated with solution 1, 2 and 3, respectively. About 30% of the ChAc was combined with its antibody during the incubation (solution 2) and this combined ChAc was inactive. There was only 59% recovery in the supernatant when the ratio of the ChAc to antiserum was 1:2 instead of 1:1. ChAc in the presence of preimmunised serum (solution 3) was more stable to prolonged incubation than in buffer alone (solution 1). This is consistent with our finding that other proteins have a stabilising effect on ChAc⁷.

Fig. 3 Immunofluorescent localisation of choline acetyltransferase in 10 μ m frozen sections of the anterior horn of bovine spinal cord. *a*, Some of three anterior horn cells and their processes fluoresce while the adjacent white matter has only scattered spots of fluorescence. Note the absence of nuclear staining in the neurones ($\times 69$). *b*, Control anterior horn section with preimmunised guinea pig serum. *c*, Same as *a* ($\times 138$).

The anti-ChAc fluorescent antibody test was carried out by procedures previously reported¹⁰. Antiserum to guinea pig γ -globulin labelled with fluorescein was purchased from Antibodies Inc., Davis, California. Preimmunised and immunised guinea pig sera were used in 1:20 to 1:80 dilutions. Lyophilised cryostat sections (10 μ m) of the anterior horns of the lumbar enlargements of bovine spinal cord were extracted with chloroform for 15 s before incubation with antiserum. This removed the bulk of the lipid without affecting the activity of ChAc⁷. The cholinergic anterior horn cells were strongly fluorescent after incubation with guinea pig serum containing antibody to ChAc and then with the fluorescent goat antiserum (Fig. 3a). There was fluorescence also in the processes of the anterior horn cells but little in the neuropil and the adjacent white matter. Control sections using guinea pig serum before immunisation with ChAc were negative (Fig. 3b). Further studies

on the immunoenzymatic localisation of cholinergic neurones in the nervous system are in progress. While this work was in progress, antibodies to rat brain were reported¹⁶.

Muscle membrane protein kinase in myotonic muscular dystrophy

MYOTONIC muscular dystrophy is an inherited disorder of man with manifestations in many organ systems including skeletal muscle myotonia and dystrophy, testicular atrophy, cataract formation, hypercatabolism of IgG, cranial bone malformations, and glucose intolerance with enhanced insulin levels (see ref. 1 for clinical references). Our previous experiments demonstrated a significant diminution in the phosphorylation of endogenous membrane proteins of frozen erythrocyte ghosts from myotonic patients¹. In subsequent studies the technique of electron magnetic resonance was employed to compare the erythrocyte membrane milieu of normal and myotonic patients². Following incorporation of 5-nitrooxide methyl stearate into erythrocyte membranes, the spin label was located in a less polar and somewhat more fluid region in myotonic membranes than in normal membranes. Although such experiments do not specify the molecular membrane abnormality or its possible relationship to protein phosphorylation, they do support the suggestion that myotonic muscular dystrophy is a disease

resulting from a basic membrane abnormality.

Erythrocytes were initially chosen for our study because of the ease of purifying membranes from normal and myotonic patients. But more significant manifestations of the disease are in muscle where numerous physiological investigations have demonstrated alterations of the surface membrane³⁻⁶. The potentially low yield of surface membrane from biopsy specimens together with the numerous secondary changes which may be unrelated to the primary disease process retarded our early biochemical investigations of muscle membrane abnormalities. With the demonstration of protein phosphorylation in purified fractions of rat muscle membrane, the technical capacity presented itself for evaluation of human biopsy material⁷. In the data to be presented below, endogenous protein phosphorylation of muscle membranes was found to be diminished in myotonic muscular dystrophy compared to control tissue. These results confirm involvement of membrane protein phosphorylation and its usefulness as a sensitive index of membrane abnormality in myotonic dystrophy.

Six patients with myotonic muscular dystrophy representing six separate families participated in the study. All of these individuals gave informed consent. Each experiment involved one patient and one control. The control muscle was obtained from patients undergoing orthopaedic operations involving femur or hip repair. None of the controls had any known muscle disease. Quadriceps femori muscle was used in all cases. The control biopsies were obtained within 1 h of patient biopsy; and both tissue preparations were fractionated simultaneously at 4° C according to a modification of the method of Brody⁸. The resultant membrane pellet consisted of a mixture of sarcoplasmic reticulum, sarcolemma, and other membrane particles. Following determination of protein concentration⁹, assessment of endogenous protein kinase activity was carried out by a modification of the methods previously used in our studies. This incubation mix contained freshly prepared muscle membranes and 50 mM sodium acetate buffer (pH 6.5); the time of incubation was 20 s. All other reagents were identical to previous studies¹⁰. Following solubilisation the polypeptides were electrophoresed on 7 1/2% SDS polyacrylamide gels. Gel staining and determination of radioactivity were performed as previously described¹⁰. Na⁺, K⁺, Mg²⁺-ATP-ase of the membrane fractions¹¹, adenyl cyclase¹² and phosphoprotein phosphatase¹ were assayed.

Washed muscle membrane preparations from both control and myotonic tissues were able to incorporate ³²P into membrane protein using only γ-³²P-ATP as a substrate. As noted previously in erythrocytes and in rat muscle preparations both the enzyme and the protein substrate seem to be endogenous components of the membrane. In each experiment the rate of incorporation of ³²P was lower in the myotonic than the control membrane. In six experiments the total myotonic membrane phosphorylation averaged 64% of control activity; and this diminution is similar to that observed in erythrocytes (Table 1).

When the polypeptide profile of the membrane preparations from control and myotonic tissue were compared, no reproducible differences were noted. Three major components were found to be phosphorylated (Fig. 1). Phosphorylation of component 1 (molecular weight approximately 90,000-100,000) was variable and after repeated washing of the membrane preparation in the Tris sucrose buffer used in membrane preparation, both the amount of component 1 relative to the other peaks as well as the phosphorylation were considerably decreased. These data suggest that component 1 is either an exogenous cytoplasmic protein or is phosphorylated by a cytoplasmic enzyme which is contaminating this crude particulate fraction.

Components 2 and 3 were readily phosphorylated and were relatively unaffected by additional membrane washes. Component 2 had a greater apparent molecular weight than component 3 respectively as assessed by SDS polyacrylamide gel electrophoresis (50,000 compared with 30,000). Component

Fig. 1 *a*, Sodium dodecyl sulphate-polyacrylamide gel scan of a typical muscle membrane preparation. *b*, Radioactivity expressed as pmol per 20 s per mg membrane protein in SDS-polyacrylamide gel fractions. Experimental blanks consisting of boiled membrane or no Mg^{2+} have been subtracted. Results are from a typical experiment. ●, Control; ○, myotonic.

2 also had a slightly greater specific activity *in vitro* phosphorylation (Table 1). In all six experiments, the rate of incorporation of ^{32}P into components 2 and 3 was lower in myotonic membranes. In both components 2 and 3, the mean phosphorylation of myotonic membranes was 50% of control preparations.

Na, K (Mg) ATP-ase activities were identical in control and myotonic membrane fractions. Similarly basal, isoproterenol, and fluoride-stimulated adenyl cyclase activity demonstrated no reproducible differences (Table 2). Phosphoprotein phosphatase activity was absent in control and myotonic membranes under the conditions used in this study.

The major limitation to evaluation of enzymatic changes of membrane fractions of human muscle tissue is the limited yield of purified fractions which may be obtained from biopsy specimens. In most studies, investigators sacrifice purity for improved yield. But when doing so as in the present experiments, one should be extremely cautious about the extent to which similar membrane preparations are being examined in the control and diseased situations. The comparable polypeptide profile as assessed by polyacrylamide gel electrophoresis, the similar Na, K (Mg) ATP-ase activity, as well as hormone and

Table 2 Adenyl cyclase and ATPase in muscle membrane preparations

	Adenyl cyclase (pmol cyclic AMP per 10 min per μg protein)			ATPase (μmol P per mg protein per h)	
	Basal	Isoproterenol (0.1 mM)	NaF Mg^{2+} (10 mM)	Mg^{2+} + Na ⁺ ATPase	K^{+} + ATPase
Control	2.24	5.19	18.8	17.8	23.7
Myotonic	3.52	6.97	15.3	17.7	23.0

Data from a typical experiment. Adenyl cyclase assay was performed on fresh tissue. ATPase was measured on tissue frozen at -20° for 2 d. Each value is the mean of duplicates. In three additional experiments no differences in control or myotonic values were demonstrated, although each experiment resulted in slightly varying activities.

fluoride-stimulated adenyl cyclase all support the comparability of the membrane preparations. Nevertheless in animal experiments by Andrew *et al.* protein phosphorylation was found in a light density membrane fraction which could be separated from fractions containing the ATPase and cyclase^{7,13}. Thus our studies contrasting protein phosphorylation must be viewed with considerable caution because of the heterogeneous origins of the fractions used.

In rat muscle preparations no polypeptide larger than 30,000 was phosphorylated. In the present studies, phosphorylation of the 90,000–100,000 molecular weight component was variably affected in myotonic muscle preparations and could be altered in both normal and myotonic preparations by extensive washing. In rat muscle tissue phosphorylation of high molecular weight components is characteristic of cytoplasmic enzymes contaminating the membrane fraction. For this reason phosphorylation of this component was felt to be less significant than that of components 2 and 3.

Phosphorylation of both of these components was significantly diminished in myotonic muscle tissue. But in these muscle membranes, the altered activity cannot be definitely attributed to a diminished enzyme because comparable activity in control and myotonic membrane components 2 and 3 could be demonstrated when the pH was raised to 7.5 and assays were carried out in the presence of Tris buffer (Fig. 2). Similar

Fig. 2 *a*, Radioactivity expressed as pmol per 20 s per mg membrane protein in fractions corresponding to proteins 2 and 3 in a typical experiment using 10 mM Na acetate pH 6.5 as the buffer system. *b*, Same experiment performed using 10 mM Tris-HCl pH 7.5. ○, Control; ●, myotonic.

Table 1 Endogenous protein phosphorylation of muscle membranes

	Myotonic (pmol per mg per 20 s)	Control (pmol per mg per 20 s)	
Total membrane phosphorylation	9.95 ± 1.1	15.9 ± 1.8	$P < 0.02$
Phosphorylation of membrane component 2	0.818 ± 0.12	1.62 ± 0.21	$P < 0.01$
Phosphorylation of membrane component 3	0.545 ± 0.10	1.09 ± 0.15	$P < 0.025$

Data from all six experiments. Total membrane phosphorylation represents the sum of all protein components. All experiments were performed in duplicate with experimental blanks (boiled membranes or reactions with Mg^{2+} deleted). Values indicated are the mean \pm s.e.m. P was determined by the Student's t test.

variations of protein phosphorylation with buffer, pH and method of membrane preparation have been observed with human erythrocytes. Since the enzymatic activity of protein phosphorylation within the membrane seems so easily affected by environmental changes, it seems more reasonable to ascribe the changes noted with myotonic muscle to an altered membrane rather than to a specific genetically mediated alteration in the protein kinase enzyme. The demonstration of lowered protein phosphorylation in muscle membranes confirms the similar observations made by us on erythrocyte ghosts. Although we were initially concerned that fibrosis, fatty infiltration, dystrophy or denervation might specifically affect the outcome, none of these seem to be particularly pertinent since morphological evaluation of the biopsies employed would suggest that minimal pathology was present in the muscle segments used. Whether the altered protein phosphorylation of muscle membrane and red blood cells or the physical alteration in the red cell membrane is the more pertinent aetiological factor is not known at present. Either of these alterations might be associated with an abnormal membrane, and both would lend support to our concept of myotonic muscular dystrophy as a diffuse disorder of membranes.

We thank Dr Robert Lefkowitz for performing the adenyl cyclase assay, Michael Herbstreith and Wink Clingenpeel for technical assistance and M. Molbert for secretarial assistance. This work was supported in part by grants from the National Institutes of Health and the National Multiple Sclerosis Society.

Structural difference in sites on surface membrane of mature and immature erythrocytes

MAMMALIAN cells transformed by oncogenic viruses or chemical carcinogens undergo characteristic changes in their surface properties such as lectin-induced cell agglutination^{1,2}. Normal cells show similar changes at their mitotic phase³ or after mild protease digestion of their surface membrane^{4,5}. This suggests that cells change their surface properties under various conditions and during the cell cycle. With this concept in mind, we studied the

Fig. 1 Con A-induced cell agglutination of rabbit erythrocytes and reticulocytes. 10^8 cells were incubated with various concentrations of con A at 37°C for 20 min. Erythrocytes (●—●); reticulocytes (○—○).

changes on the membrane surface during the maturation of rabbit erythrocytes. We describe here the changes in cell agglutinability and in the binding sites of concanavalin A (con A) on the cell surface during erythrocyte maturation.

Reticulocytes were obtained from phenylhydrazine-injected rabbits⁶. Rabbit erythrocytes and reticulocytes were washed three times with glucose-free Hanks' balanced salt solution (HBSS). Con A and ^{125}I -labelled con A were obtained as described previously⁷. Cells were scored for agglutination on a qualitative scale from - to +++++ after 20 min incubation at varying temperature with an appropriate concentration of con A (ref. 7). The binding of ^{125}I -con A (672 c.p.m. per µg con A) was carried out at 37°C for 10 min with or without 100 mM α -methyl-D-glucoside (α -MG)⁷.

Reticulocytes agglutinated at much lower concentrations of con A at 37°C . Even at $5\mu\text{g ml}^{-1}$ con A, reticulocytes showed marked agglutination, whereas no agglutination was observed in the case of erythrocytes (Fig. 1).

The agglutination of both these cells was temperature dependent (Fig. 2). Erythrocyte agglutination was, however,

Fig. 2 Temperature-dependent agglutination of rabbit erythrocytes and reticulocytes. The concentration of con A used was $75\mu\text{g ml}^{-1}$. Other conditions as in Fig. 1. Erythrocytes (●—●); reticulocytes (○—○).

Fig. 3 Binding of ^{125}I -con A to rabbit erythrocytes and reticulocytes. 10^8 cells were incubated with varying concentration of ^{125}I -con A at 37°C for 10 min, with or without 100 mM α -methyl-D-glucoside, and were washed three times with HBSS. Erythrocytes (●—●); reticulocytes (○—○).

induced only at temperatures above 15°C whereas reticulocyte agglutination was observed even below 10°C . The difference in the agglutinability and in the temperature-dependence of these two cell types may be due to the difference in the number of surface receptors for con A.

The number of ^{125}I -con A binding per cell was, however, almost equal for each cell type (Fig. 3). This suggests that membrane changes other than the number of con A binding sites are likely to account for the difference in the agglutinability of these cells. The differences we have observed parallel the difference in the agglutinability of normal and transformed cells, and may be caused by the difference in membrane fluidity and/or topographical distribution of con A receptor sites on the cell surface. We are now doing a comparative study on surface structure and membrane components to understand the changes which occur during erythrocyte maturation.

Isolation of a collagen-dependent cell attachment factor

Most untransformed mammalian cells require an appropriate surface for survival and growth *in vitro*; this phenomenon has been termed anchorage dependence¹. Glass, tissue culture plastics, fibrin clots and collagen surfaces have long been recognised as substrates able to support the attachment and growth of cells. Since the cell plasma membrane is separated from plastics substrates by a 450 Å layer of electron opaque material², the nature of the 450 Å would appear to be more important in cell attachment than the chemical composition of the plastic. It is demonstrated here that cell attachment to collagen is mediated by a high molecular weight protein present in serum.

Petri plates were coated with collagen as described in the legend to Fig. 1. When 2×10^5 SV-3T3 cells were added to collagenised Petri plates and incubated in the presence of serum for 1.5 h, the number of cells attached increased as the percentage of calf serum was increased from 0.03% to a plateau level at 3% (Fig. 2). Cell spreading was observed in the 10% and 3% points in 1.5 h. The sum of the attached and unattached cells (*a*) varied slightly with serum concentration and (*b*) was consistently slightly less than the number of cells inoculated (this may have been due to lysis of injured cells). By varying the time of the incubation, it can be seen that cell attachment started after 5 min, and continued for 6 h (at which time cell growth started in the high serum points) (Fig. 2*a*). The number of units of attachment factor, as defined in the legend to Fig. 1, varied as a linear function of time (Fig. 2*b*). The number of units of attachment factor did not vary greatly when the number of cells inoculated ranged from 1.5×10^6 to 2×10^5 (Fig. 3). It should be noted that the number of units of attachment factor varied between different commercial lots of serum.

The ionic requirements for cell attachment were determined by omitting components from Eagle's medium. Cells attached and spread in a medium consisting of NaCl, KCl (Mg^{2+} , or Ca^{2+}), glucose (at concentrations found in Eagle's medium) and 10 mM Hepes (pH 7.5) (no CO_2 or bicarbonate were used). The minimal attachment medium was 65% as effective as Eagle's medium as determined from the ratio of units of attachment activity in both media (omission of glucose or KCl results in less effective cell attachment). Cell attachment depended on either Mg^{2+} or Ca^{2+} , whereas Sr^{2+} and Ba^{2+} were inactive in the assay (Fig. 4). The pH optimum for cell attachment is in the physiological range, between pH 6.0 and 8.5 (high pH results in precipitation of Ca^{2+} and Mg^{2+} as their hydroxides).

The attachment factor was purified by batch preparation procedures as described in Table 1. The DEAE purified factor (Fig. 5) was half inactivated by treatment for 5 min at 65°C and had a pH of 4.8 (Fig. 6). Purified attachment factor (DEAE step) was stable to treatment at 37°C for 16 h with $10 \mu\text{g ml}^{-1}$ of either trypsin or pronase. The factor seemed to be of molecular weight greater than 200,000 since it was eluted at the void volume of both Sephadex G-100 and G-200 columns.

The rate of binding of attachment factor to collagen was assayed by (*a*) exposing air-dried collagenised plates to a series of dialysed cell attachment factor (second AmSO₄ step) concentrations in the presence of 0.9% NaCl (*b*) washing the plates eight times (2 min per wash) with 0.9% NaCl to remove unbound factor and (*c*) assaying cells in Eagle's medium without serum in order to determine the amount of factor that has been bound to the collagen. Figure 8 demonstrates that factor binds rapidly to collagen in the absence of divalent actions. Up to 30 min, the amount of factor bound increased linearly with time; the non-linearity in factor binding after 30 min may have been due to an increase in the number of collagen binding sites as the air-dried collagen swelled slightly during rehydration.

Fig. 1 Top, Petri plate washer, made from plastic box and bottom of a Rubbermaid (No. 6049) dish drainer; Middle, Petri plate tray; Bottom, Rubbermaid plastic boxes for saline and discarded solutions (used in washing Petri plates at the end of the assay); Bottom, Petri plate decanter, made from spring-loaded pants clamps and metal rod. Petri dishes were coated with collagen as follows. Collagen was prepared by acid extraction, and salt and ethanol precipitation^{4,6}. Freshly dissected rat tail tendons (8 g) were stirred overnight in 1 l of 0.2% citric acid and insoluble material was removed by filtration on a Buchner funnel. Collagen was precipitated by adding 10% (w/v) NaCl and was spun down at 10,000g for 15 min. The white precipitate was solubilised by stirring it in 0.2% acetic acid for several hours. The collagen solution was reprecipitated by adjusting the pH to 8.0 with NH_4OH , adding 20% (v/v) ethanol, and pelleting at 10,000g for 15 min. The collagen was lyophilised and stored for up to 6 months at 15° C. Bacteriological Petri plates (Falcon No. 1007) were coated with collagen by placing the bases in a large plastic tray and dispensing into them 1.5 ml of 0.25% collagen in 0.2% acetic acid plus 0.002% phenol red with a 2-ml Cornwall pipetter. After rocking the tray to ensure uniform coating, the collagen was gelled by placing a partially NH_4OH -soaked, cloth-lined lid over the tray. The plates turned a metallic red colour in 5-10 min, when the lid was removed and the plates were air-dried. To reduce control levels in the assay, the completely air-dried plates were treated with 8 M urea for 20 min in Petri plate washing trays. The bottoms were washed three times with distilled water (5 min per wash) and then air-dried. The collagen-coated plates can be stored at room temperature for at least 2 months.

Fig. 2 Cell attachment assay. 2×10^6 cells were incubated at 37° C for 1.5 h on collagenised plates in the presence of serum. \blacktriangle , attached cells; \blacksquare , unattached cells; \bullet , attached + unattached cells. Petri plates were loaded with 5 ml of Eagle's minimal essential medium (Gibco catalogue No. F-11) containing $200 \mu\text{g ml}^{-1}$ bovine serum albumin (Sigma) with the required amount of serum or factor and preincubated at 37° C in a 5% CO_2 in-air incubator for 1 h (to allow the factor to bind to the collagen). Generally, serum concentrations in increments of one-half decade from 0.001% to 10% serum were used. During the Petri plate preincubation, semiconfluent SV-3T3 cells were (a) detached by a 15 min trypsinisation at 37° C with 0.25% Bacto-trypsin (Difco) and (b) washed twice in serum free Eagle's medium containing $200 \mu\text{g ml}^{-1}$ bovine serum albumin. After the Petri plate preincubation, 2×10^6 washed cells were added to each plate and incubated at 37° C in a CO_2 incubator for 1.5 h. Petri plates were emptied with the Petri plate decanter (Fig. 1), filled with 0.9% NaCl, decanted again and trypsinised for 10-15 min with 5 ml of 0.25% trypsin. The cells removed from the collagen were then counted with an electronic cell counter. Two samples of serum were compared with respect to cell attachment factor activity by (i) making serial half decade dilutions of the two samples and (ii) determining that percentage of serum which attaches 50% of the cells attached in the 10% serum controls. A unit of attachment factor is defined as the reciprocal of that percentage of serum that attaches half of the cells attached in the 10% serum controls (unit = $1/\%$ serum $_{1/2}$). The reciprocal of serum concentration is used to assign a higher number to a more active sample. The use of reciprocals does not change the magnitude of the ratio of activities, since $x/y = (1/y)/(1/x)$. As defined, the unit of attachment factor is proportional to the concentration of factor; the unit's dependence on time of incubation and number of cells used is given in the text.

Fig. 3 Time course of cell attachment on collagen. \times , 5 min; Δ , 10 min; \circ , 15 min; \square , 30 min; \blacktriangle , 1.5 h; \blacksquare , 3 h; \bullet , 6 h.

The process of cell attachment to collagen can be divided into at least two steps. (1) A high molecular weight serum protein must bind to collagen; and (2) a divalent cation-dependent reaction is required for cells to attach to the collagen-serum factor complex. These steps can be distinguished from each other since the serum factor binds to collagen in the absence of divalent cations or cells; whereas, cells bind to factorised collagen only in the presence of Ca^{2+} or Mg^{2+} . Cell spreading on a collagen substratum may be mediated by the cell attachment factor, described here, since column fractions which mediate cell attachment also have cell spreading activity.

Collagen's role as a cell substratum may be identified as one of its major physiological functions from the following evidence. First, biochemical methods indicate that collagen represents 20% of total protein in mammalian tissues, with the exception of the nervous system³. Second, it is well known that collagen is found intracellularly in many tissues^{3,4} and is

Fig. 4 Relationship between units of attachment factor and time (○).

Fig. 5 2×10^5 (▲), 7.5×10^5 (■) and 1.5×10^6 (●) cells were incubated on factorised collagen for 3 h. More cells attached in low percentage serum when a high cell density was used than at high percentage serum when a low cell density was used.

Fig. 6 Divalent cation requirement for cell attachment to collagen. 2×10^5 cells were incubated at 37°C in a medium consisting of NaCl; KCl; glucose (at Eagle's medium concentrations); 10 mM Hepes, pH 7.5; 10% calf serum equivalent of the DEAE purified factor (as assayed in complete Eagle's medium); and various divalent cations. No CO_2 was used to avoid the precipitation of carbonates. ○, Mg^{2+} ; ■, Ca^{2+} ; ●, Sr^{2+} or Ba^{2+} .

Table 1 Batch preparation of serum factor

Step	Total vol (ml)	Total protein (280nm; 1 cm path length) (fractions diluted to 1x calf serum)	Total units	Specific activity (units/280nm)	Recovery	Purification
Calf serum	1,000	71	14,300	201	—	1
1st PEG	200	20.16	14,300	711	100%	3.55
1st AmSO_4	200	8.4	12,500	1,488	87%	7.4
2nd PEG	200	5.4	10,000	1,851	70%	9.2
CaPi gel	400	2.2	1,940	882	13.6%*	4.4
2nd AmSO_4	50	1.32	3,300	2,500	23%	12.5
DEAE-11	90	0.30	2,500	8,350	17.5%	41.8

The serum attachment factor was purified from calf serum by batch preparation method. 1st PEG (0→4.5% PEG): using plastic labware to which PEG does not stick, 100 ml of a 50% (w/w) solution of polyethylene glycol-6000 (PEG) (Baker) solution was added to 1l of calf serum at 4°C. The precipitate which had formed in 30 min was spun down at 18,000g for 30 min and dissolved in 200 ml of 0.1 M imidazole + 0.15 M NaCl (pH 6.8) (standard buffer). 1st AmSO_4 (0→28.6% AmSO_4): 80 ml of saturated $(\text{NH}_4)_2\text{SO}_4$ was added slowly at 4°C to 200 ml of the 1st PEG material; after 20 min, the precipitate was collected by centrifugation at 18,000g for 15 min and dissolved in 200 ml of standard buffer. 2nd PEG (1→4.5% PEG): 4 ml of 50% PEG was added to 200 ml of the 1st AmSO_4 cut, and after 30 min the precipitate was removed by centrifugation at 18,000g for 10 min. 16 ml of 50% PEG was then added to the 1% PEG supernatant; after 30 min, the precipitate was collected by centrifugation at 18,000g for 20 min and dissolved in 200 ml of a standard buffer. CaPi gel: calcium phosphate gel (Brushite) was prepared according to Levin⁶. 200 ml of CaPi was added with stirring to 200 ml of the 2nd PEG material at room temperature. After 30 min, the gel was (i) spun down at 5,000g for 10 min; (ii) resuspended in 200 ml of 0.1 M aspartate (pH 6.8); (iii) spun down at 5,000g for 10 min, and (iv) eluted twice with 200 ml of 0.5 M aspartate + 0.1 M imidazole + 0.15 M NaCl (pH 6.8). 2nd AmSO_4 (0→30% AmSO_4): to the 400 ml of combined eluate was added 320 ml of saturated $(\text{NH}_4)_2\text{SO}_4$ at 4°C; the resulting precipitate was spun down at 18,000g for 15 min, and redissolved in standard buffer to a final volume of 50 ml. DEAE-11 chromatography: 25 ml of the 2nd AmSO_4 material was diluted to 100 ml with cold water and precipitate which had formed in 30 min was removed at 10,000g for 10 min. The soluble material was then applied to a 4.5×20 cm DEAE-11 column which had been washed with 0.5 M KH_2PO_4 (pH 6.8) and 200 ml of one-quarter strength standard buffer. The column was then washed with 60 ml of 0.25 M standard buffer. The active material was eluted with 1l of 0.25 M NaCl + 0.1 M imidazole (pH 6.8) and the active peak was pooled (Fig. 5).

Fig. 7 DEAE-11 chromatography of 2nd AmSO_4 fraction. At each arrow, the following solutions were added to the 4.5×20 cm column: (A) 100 ml of diluted factor; (B) 60 ml of 0.25 strength standard buffer; (C) 200 ml of 0.65 strength standard buffer; (D) elution with 1l of 0.25 M NaCl + 0.1 M imidazole (pH 6.8). Tubes 52 to 60 were pooled.

Fig. 8 Isoelectric focused in a LKB 110 ml column, in a sucrose gradient containing 1.4 ml pH 3-6 LKB ampholytes and 0.14 ml pH 3-10 LKB ampholytes.

Fig. 9 Binding of purified attachment factor to collagen in the absence of divalent cations or cells. Collagenised plates were treated with a series of dialysed factor concentrations in 0.9% NaCl and treated as described in the text. The washed plates were assayed for attachment activity in Eagle's medium (with Ca^{2+} and Mg^{2+} + $200 \mu\text{g ml}^{-1}$ bovine serum albumin).

Effect of zinc on haemoglobin binding by red blood cell membranes

RESULTS of recent studies in our laboratory have suggested that zinc plays an important role in sickle cell anaemia. A significant proportion of sickle cell patients are zinc deficient¹. Zinc binds to haemoglobin and increases oxygen affinity^{2,3}. Sickle cells treated *in vitro* with zinc show markedly improved filterability at concentrations too low to be explained on an oxygen affinity basis⁴, and zinc may interact with the membranes to affect filterability. A recent report suggests that sickling involves the accumulation of calcium⁵ which is known to reduce red cell membrane deformability⁶. We have now found that zinc decreases the amount of haemoglobin associated with red cell membranes and inhibits the effect of calcium in causing haemoglobin retention by membranes.

Single stage red cell membranes were prepared by the technique of Hoffman⁷ with minor modifications. Agents to be incorporated into these membranes were added during

produced by most tissue culture cell lines⁵. Finally, cell attachment to collagen has been shown here to depend on physiological parameters; namely, a requirement for divalent cations as well as a specific high molecular weight protein.

I thank Dr Robert W. Holley for encouragement and suggestions. I was a postdoctoral fellow of the Jane Coffin Child Memorial Fund for Medical Research. The investigation was aided by grants from the National Institutes of Health and the US National Science Foundation.

Table 1 Haemoglobin retention by ghost cells

Sample type	Hb (g% in initial packed cells)	Hb (g% in final ghost pellet)	Mean cell volume (μm^3)	Hb (g% corrected for change in MCV)	% Retention of Hb	t test
No addition (control)	25.21 \pm 1.8	1.86 \pm 0.6	73.6 \pm 1.9	1.86 \pm 0.6	7.4 \pm 2.5	$t = 6.3$ $P < 0.001$
ZnSO ₄ ghosts	24.94 \pm 0.8	0.79 \pm 0.2	22.9 \pm 2.5	0.25 \pm 0.1	1.0 \pm 0.3	
CaCl ₂ ghosts	25.81 \pm 1.0	21.79 \pm 2.4	21.5 \pm 1.6	6.39 \pm 0.9	24.6 \pm 4.1	$t = 4.5$ $P < 0.01$
CaCl ₂ + ZnSO ₄ ghosts	24.48 \pm 2.1	10.41 \pm 4.0	22.1 \pm 2.3	2.50 \pm 0.5	10.7 \pm 2.6	

All values are the mean \pm 1 s.d. of four observations. ZnCl₂ had approximately the same effects when substituted for ZnSO₄.

haemolysis. The principle of this technique is based on the knowledge that erythrocyte membranes lose their selective permeability at haemolysis and immediately thereafter, facilitating the introduction of various normally nonpenetrating compounds into the cells^{8,9}. In our experiments normal red cells to be haemolysed were divided into four aliquots and treated as follows: no addition (control), zinc sulphate (1.5 mM), calcium chloride (1 mM), and calcium chloride (1 mM) plus zinc sulphate (1.5 mM). Hypotonic exposure lasted 20 min. In all but the control aliquot enough sodium chloride was added to achieve the same ionic strength as the calcium chloride plus zinc sulphate solution. After hypotonic exposure with 10 volumes of water the red cell membranes were resealed with isotonic saline-0.01 M Tris buffer, pH 7.4, and washed until the supernatant was clear of haemoglobin. The haemoglobin in these ghost cell preparations was measured by the cyanmethaemoglobin method. The size and the mean cell volume (MCV) of the ghost cells were calculated using a Coulter counter with multichannel particle size analyser and recorder. Haemoglobin concentrations in the membrane preparations were corrected for the decreased size of the red cell membranes compared with original red cells, since shrinkage of these ghost cells results in some increase in concentration of entrapped haemoglobin.

Table 1 shows that the amount of haemoglobin retained in the membrane preparations after final washing was much less in the presence of zinc compared with control membranes. In the presence of calcium a large amount of haemoglobin was retained, as reported before^{10,11}. When zinc was present together with calcium, however, much less haemoglobin was retained compared with calcium alone, although in both cases the membranes were similar in size (both were small). Equimolar concentrations of lanthanum chloride, but not magnesium, also decreased the haemoglobin-retaining effect of calcium in these preparations (data not shown).

Calcium is known to interact with the interior of the red cell membrane, altering its configuration, decreasing passive permeability¹⁰, decreasing deformability^{6,11} and increasing haemoglobin retention^{10,11}. Zinc seems to counteract the retention of haemoglobin by red cell membrane both in the presence and absence of added calcium. One effect of calcium may be to crosslink haemoglobin and membrane sites. If so, calcium may be involved in the pathogenesis of irreversibly sickled cells by promoting such crosslinking. It is tempting to speculate that zinc improves the filterability of sickle cells, and promotes the elution of haemoglobin from red cell membranes, by blocking our hypothesised calcium-induced crosslinking of haemoglobin to membranes.

Nuclear segregation in *Bacillus subtilis*

JACOB, BRENNER AND CUZIN¹ suggested that prokaryote nuclear segregation was achieved by cell surface extension between surface sites to which the chromosome is permanently attached (Fig. 1a). Their model (model A) showed nuclear segregation occurring in newly divided cells, with all surface extension in one cycle occurring between the nuclei. Thus at cell division, nuclei would be arranged symmetrically in the half cell but asymmetrically during the interdivisional period. If nuclear segregation occurs during mid-cycle and cell extension is continuous throughout the cycle, the nucleus cannot reach a symmetrical position (that is at 25% of the cell length) by the end of the cycle relying solely on length extension. To overcome these difficulties, Clark² proposed that the nucleus is always located at the junction of old and new membranes with growth occurring on one side of the nucleus (model B, Fig. 1b). At nuclear segregation, the growing point divides allowing growth of the cell envelope between the nuclei as shown in Fig. 1b. Nuclei remain attached at the site of envelope extension, giving a newborn cell with an asymmetrically arranged nucleus. Donachie and Begg³ have presented evidence for terminal growth regions in slow growing cells as predicted by Clark's model. A third possibility is that the nucleus is located centrally in new born cells and moves to a position at the centre of a half cell at the time of segregation (model C, Fig. 1c). These, and other possibilities, can be explored by determining the position of nuclei in relation to cell length in exponential phase cells.

Bacillus subtilis (168/S) (an asporogenic derivative of 168 tryp⁻ thy⁻ able to grow on succinate as sole carbon

source at a generation time of 115 min) was grown in either succinate or glucose based minimal medium to minimise the cell separation time⁵ and to give substantial numbers of mononucleate cells⁴. Using Giemsa, nuclei appeared as small spherical dark blue bodies in a pale pink-to-colourless cytoplasm. The number and appearance of nuclei was highly reproducible under constant cultural conditions. Cells contain an average of 1.3 and 1.8 nuclei per unit on succinate and glucose media respectively. Each bacterial particle has been regarded as a unit even while containing a septum. The time interval between nuclear segregation and cell separation, calculated from the age distribution theorem⁵ is 48.5 and 45 min for succinate and glucose (generation times 115 and 57 min). Large numbers of cells were photographed and, from the negatives projected on to a screen, positions and diameters of nuclei and lengths of cells were determined. Less than 5% of any population could not be scored because of poor staining and a slightly larger proportion was discarded that were not in focus. All measurements of the position of nuclei were taken from the distal edge of the nucleus to the centre of the cell. These data are shown in Fig. 2.

The critical difference between model C and the other two is the abrupt transition of the nucleus from the centre of the cell to the centre of the half cell. If nuclei move apart gradually at early stages of segregation the nuclear attachment sites should be sufficiently close that nuclei would overlap and be scored as one larger than average nucleus. When plotted against cell length, the distance between cell centre and the distal edge of the nucleus should vary continuously as the two nuclei become visible. Figure 2 indicates that this is not so, and in fact the distal edges of nuclei of 85% of binucleate cells are at least 2.5 radii from the cell centre. Nuclei vary only slightly in size between mononucleate and binucleate cells. The best line connecting binucleate and mononucleate cells has a slope of about 1.5 in both media indicating that the nucleus moves along the cell apparently three times faster than the rate of length extension. The frequency distribution of distances from the cell centre to centre of nuclei are shown for two size classes of binucleate cells in Fig. 3. The peak for all cells is between 20 and 24% from the centre, but there is a skew towards the centre in smaller cells. The data are shown relative to the average nuclear radius of mononucleate cells and there is only minimal overlap between mono and binucleate cells. The peak of the distribution of distance from the cell centre is slightly less than 25%, possibly because

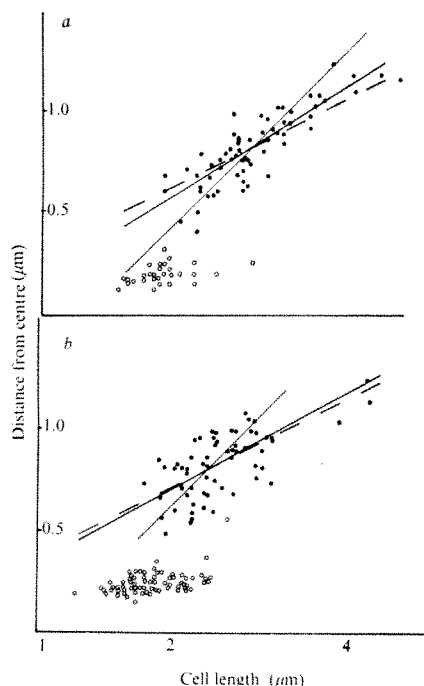

Fig. 2 Position of nuclei relative to cell length. *a*, Glucose grown cells (96 units in sample); *b*, Succinate grown cells (247 units in sample). To stain the nuclei, bacteria were heat fixed onto glass slides, treated with 1 N hydrochloric acid at 60°C for 7 min, washed in phosphate buffer (pH 7.4), and stained with Giemsa (diluted 1:10 with distilled water) for 5 min. ●, Binucleate cells; ○, mononucleate cells; —, graph of 25% of cell length; —, graph of 50% of cell length; —, line of best fit (obtained by method of least squares) for distal edge of nucleus. Regression coefficients for the glucose grown cells (*a*) for distal edge and nuclear centre respectively were 0.31 (significantly different to 0.25 at 1% probability using Student's *t* test) and 0.27 (not significantly different at 5% probability) respectively. The correlation coefficients were 0.87 and 0.76 respectively. Regression coefficients for the succinate grown cells (*b*) for distal edge and nuclear centre respectively were 0.25 and 0.23 and were not significantly different to 0.25 at 5% probability. The correlation coefficients were 0.67 and 0.65 respectively.

Fig. 1 Models of nuclear segregation in bacteria. *a*, The model of Jacob, Brenner and Cuzins¹ (model A). All surface growth occurs between the nuclei. *b*, The model of Clark² (model B) in which nuclei are rigidly attached to a particular site and growth occurs only to one side of the nucleus. *c*, An alternative model (model C) in which nuclei move to a site 25% of the cell length from the poles. Surface growth occurs to both sides of the nucleus. Most intense stippling indicates newest cell envelope.

cell length has been systematically slightly overestimated. As less than 5% of mononucleate cells show any deviation from the centre of the cell, the nuclei are probably located at 25% from the cell centre immediately before cell division.

Model B proposes that nuclei should be arranged asymmetrically in most cells of an exponential population. Less than 5% of mononucleate cells show any asymmetry on either medium, and the data in Fig. 3 indicate that nuclei of most binucleate cells are arranged symmetrically in each half cell.

Model C differs from A and B in the slope of the line relating nuclear position with cell length. Models A and B predict a slope of 0.5 whereas model C predicts a slope of 0.25. Although for both sets of data the scatter is considerable, the data favour model C rather than A or B (Fig. 1). Using autoradiography, Mendelson⁶ has shown that nuclei in binucleate cells of *Bacillus subtilis* 168 are predominantly 25% from either pole but mononucleate cells were not included in his analysis.

The rapid transition (less than 6 min) indicated by these data may be illusory, as in growing cells the nucleus may be arranged more diffusely than stained preparations suggest. If so, the location of the fixed nucleus probably represents the focus of the chromosomes' strongest interactions with the cell surface. The nucleus, however, may form a loose link with a new site earlier in the cell cycle. In *Escherichia coli*, segregation occurs close to the time of

Fig. 3 Frequency distribution of distances from cell centre to centre of nuclei. *a*, Data from Fig. 2*a*. —, Data from binucleate cells less than 2.8 μm long. ---, Cells of greater length. *b*, Data from Fig. 2*b*. —, Binucleate cells less than 2.6 μm long. ---, Cells of greater length.

Fig. 4 Postulated origin of cell surface for a cell at division. Length of zone calculated assuming linear rate of surface extension from sites occupied by nuclei and that segregation occurs at mid-cycle (S, septum). *a*, Synthesised in interval between segregation and cell division; *b*, synthesised before segregation in current cycle; *c*, synthesised in interval between segregation and cell division in previous cycle; *d*, synthesised before segregation in previous cycle.

chromosome termination⁷ and this may represent the signal for pre-existing weak interactions with new sites to become predominant.

If the site of nuclear attachment is a major site of cell envelope extension and the rate of length extension is linear at each growth zone, the pattern of surface growth shown in Fig. 4 follows from the pattern of nuclear segregation in model C. The diagram shows the postulated distribution of cell surface synthesised during four periods for a cell which is about to divide. Lengthwise growth between segregations (Fig. 4*b* and *c*) must equal half the length of a cell at segregation. Therefore, if nuclei move 25% of the cell length, they would move to the junction of old and new surface formed one generation previously. As this was the site occupied by the nucleus at the time of the previous segregation, 'the pre-existing weak interactions', discussed here, may have been established at this time.

Chronic response of dogs to parathyroid hormone infusion

WHEN parathyroid hormone is infused chronically at a near-physiological rate, it causes hypercalcaemia by a mechanism fundamentally different from that which follows acute injections. Hormones, like drugs, have characteristic rates of metabolism and excretion and their distribution in the body is affected by binding to plasma proteins and membranes. Thus similar dependence of the pattern of response on entry rate is to be expected in the case of other hormones with short half lives, acting on multiple receptors of varying sensitivity.

As discussed in a recent review¹, parathyroid hormone (PTH) is an 84-residue single-chain polypeptide, which is probably secreted continuously at a rate regulated by the calcium concentration of the plasma. Its principal function seems to be to raise the calcium concentration in the plasma and extracellular fluid. Most of its multiple actions contribute to this effect and the rate of secretion of the parathyroid glands is inversely related to the circulating calcium concentration, providing close negative feedback control of the plasma calcium level. PTH accelerates bone breakdown and increases renal calcium retention and intestinal calcium absorption, this being the order of relative contribution of these actions to the hypercalcaemia elicited by injecting a large dose. Consideration of their individual dose-response curves, however, suggested a very different relative importance in normal physiology and led us to make a direct test of the effects of infusing minute doses continuously for periods of several weeks.

A miniature syringe-type pump (the Mill Hill infuser) was developed for us by the Engineering Division of the National Institute for Medical Research to enable continuous infusion during investigations and experimental therapy in freely mobile patients and large animals². Large dogs, whose calcium metabolism is similar to that of man, were equipped with indwelling cannulae in the external jugular vein³ and trained to wear the infusers on a light leather harness. Two cannulae were used, a technique permitting withdrawal of large well-mixed blood samples without interruption of the hormone infusion.

The results of infusions lasting up to 3 weeks are illustrated in Fig. 1. A dose rate of 25 ng kg⁻¹ h⁻¹ (0.05 U kg⁻¹ h⁻¹) continued for 3 d left the plasma calcium level of two dogs unchanged, but 100 ng kg⁻¹ h⁻¹ caused marked hypercalcaemia in each of four animals, reaching a plateau within 24 h and continuing throughout the infusions.

These results permit conclusions that could not be drawn from experiments by subcutaneous injection, in which the rate of absorption and the extent of local destruction of the hormone are both uncontrolled. For example, they make possible an estimate of the plasma level of intact PTH required to produce marked hypercalcaemia. From published estimates of the half time of disappearance of intact PTH (approximately 0.1 h (refs 8–10)), it can be calculated that an infusion of 0.1 µg kg⁻¹ h⁻¹ could only support an equilibrium circulating level of about 30 pg ml⁻¹ of intact hormone. From the 'black box' relationship: content at equilibrium = (entry rate × $t_{1/2}$)/0.693. Content is converted to concentration by assuming distribution throughout body water (50% of body weight). This estimate of the hypercalcaemic level is strikingly lower than present radioimmunoassay estimates of the PTH level in normal health (for example 1 ng ml⁻¹ (ref. 11)). The discrepancy underlines the fact that immunoassays can estimate biological activity only very indirectly. For example, biological activity of PTH is associated with N-terminal fragments, whereas current immunoassays for this hormone measure principally C-terminal fragments of long half life^{1,12,13}.

The results in Fig. 1 also give an indication of the normal rate of parathyroid secretion. The hypercalcaemia shows that the circulating level of bioactive PTH must have been greatly increased by infusion of 100 ng kg⁻¹ h⁻¹, although on immunoassay evidence the output of the animal's own parathyroids was presumably reduced virtually to zero at the calcium concentration reached^{1,14}. Copp and his colleagues¹⁵, using crude parathyroid extract, estimated that the dose required to maintain plasma calcium in acutely parathyroidectomised dogs kept under anaesthesia was 0.1 U kg⁻¹ h⁻¹. This estimate of the endogenous secretion rate is close to that which the present evidence suggests, in spite of the many differences in method.

At first sight the evidence obtained on the mechanisms contributing to hypercalcaemia at this low level is surprising. For example, signs of osteolysis were looked for in bone biopsy samples from the iliac crest before and after each infusion and alcohol-soluble hydroxyproline was measured in the plasma (an index of collagen breakdown¹⁶ which correlates closely with bone destruction^{17,18}). The biopsies, examined by Darby⁴, showed no increase in osteoclast numbers or in the areas involved in resorption and the hydroxyproline levels did not increase during hypercalcaemia in any of the four animals (Table 1).

Little support, however, can be found for the assumption that the acceleration of bone breakdown is a normal physiological response to parathyroid hormone. It occurs in patients with an actively secreting parathyroid adenoma and is known to be a direct effect of exposing bone to high concentrations of PTH (ref. 1). But the doses required to elicit a half-maximal hypercalcaemic response involving calcium mobilisation from bone are of the order of

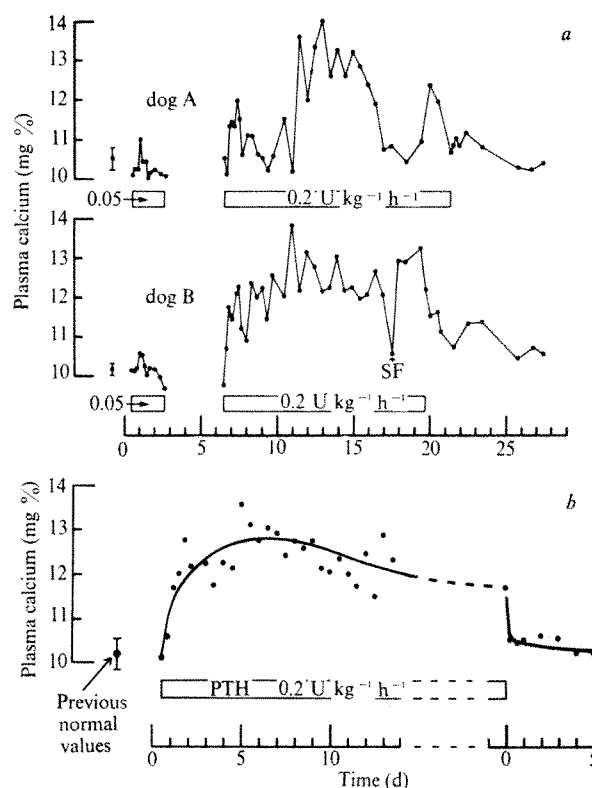

Fig. 1 *a*, Plasma calcium levels of two dogs during and after infusions of highly purified bovine parathyroid hormone at 25 and 100 ng kg⁻¹ h⁻¹ (0.05 and 0.2 MRC units kg⁻¹ h⁻¹). Horizontal bars indicate the duration of the infusions, which were separated by an interval of 3 d. The mean and s.d. of the plasma calcium level during 5 d preceding the first infusion is shown on the left. The letters SF denote a temporary syringe failure. Preliminary descriptions of these experiments were presented at the Endocrinology 1973 meeting⁴ and the Tenth European Symposium on Calcified Tissues⁵. Infusions were carried out at 2 ml per 24 h, in a vehicle consisting of 10% dog serum in 1% (w/v) sodium acetate trihydrate. This was heated at 56° C for 1 h (pH ≈ 7) to destroy proteolytic enzymes, adjusted to pH 4 with concentrated HCl, sterilised by membrane filtration (Millipore membranes, mean pore size 0.45 µm) and stored at -20° C. It is a nonantigenic variant of the vehicle used in our laboratory for bioassay of parathyroid hormone⁶. PTH dissolved in this vehicle at only a few µg ml⁻¹ was shown by the intravenous chick assay to be protected from surface absorption and to be stable for at least one week at room temperature. Calcium and phosphate analyses were carried out by atomic absorption spectrophotometry⁷ and had a coefficient of variation of less than 1%. *b*, Mean values of the plasma calcium level at corresponding times during infusions at the hypercalcaemic rate (100 ng kg⁻¹ h⁻¹) to four dogs. As two infusions lasted for 2 weeks and two for 3 weeks, the time scale is interrupted and restarts at the end of the infusions. The solid line is drawn to give an overall impression of the average effect, emphasising the slow onset of hypercalcaemia and the rapid fall in calcium level which followed termination of the infusion in all dogs. This time course is consistent with the known slowness of induction of enhanced intestinal absorption and rapid recovery from the renal action¹. PTH, parathyroid hormone.

20 U kg⁻¹ in dogs³ and 50 U kg⁻¹ in chicks⁶—both sensitive species. Experiments including potentiation of the PTH response with a small intravenous calcium injection suggest that the slow osteolytic process is initiated by (and long outlasts) a very rapid cellular response involving calcium influx¹ as well as activation of adenyl cyclase¹⁹, but these responses required doses of hormone corresponding to initial plasma levels thousands of times greater than the hypercalcaemic level calculated above for the present infusion study.

The hypercalcaemia due to infusion of 100 ng PTH kg⁻¹ h⁻¹ therefore presumably involves more sensitive responses and we looked for effects on calcium absorp-

tion and excretion. The calcium absorption coefficient (α =calcium absorbed/calcium ingested) was measured by giving ^{47}Ca by mouth and ^{45}Ca intravenously²⁰ and following the isotope ratio in plasma until it became constant. Analysis of urine from these large dogs was achieved only by housing two of them in metabolic cages for 24 h and comparing the concentrations of calcium and creatinine.

A striking effect on calcium absorption was observed during each infusion, α rising to between two and four times control values⁴. This action of PTH is well established¹, but its relative sensitivity was previously unknown. Its mechanism may involve enhanced production of 1,25 dihydroxycholecalciferol, a biologically active metabolite of vitamin D (refs 21 and 22) and induction of the vitamin D-dependent calcium-binding protein described by Wasserman and Taylor²³.

The urinary calcium: creatinine ratio fell during PTH infusion in both dogs studied, in spite of the marked hypercalcaemia and consequent increase in filtered load. This calcium-retaining action of the hormone is also well established¹ and was recently studied in dogs by micropuncture during infusion of $2 \text{ U kg}^{-1} \text{ h}^{-1}$, a dose which greatly enhanced distal tubular reabsorption²⁴. Interestingly, the phosphaturic action of PTH has a proximal tubular mechanism²⁵, so presumably there are two anatomically separate sets of PTH receptors in the kidney alone. Although phosphaturia is known to be evoked by lower doses than bone breakdown²⁶, neither urine nor plasma phosphate concentrations changed during the present infusions.

Table 1 Plasma hydroxyproline ($\mu\text{g ml}^{-1}$)

Dog	Control	During hypercalcaemia
A	7.2	7.2
B	4.2	3.0
C	3.5	3.2
D	4.5	4.0

Heparinised plasma for analysis (1.5 ml) was obtained by pooling aliquots from 3–5 successive days during control or infusion periods, each sample having been separated within 30 min and stored at -20°C . Non-protein bound (alcohol-soluble) hydroxyproline was measured by the method of Le Roy, *et al.*¹⁶.

These findings suggest the need to reassess current views of the biological role and clinical significance of parathyroid hormone. The contrast between the effects of administration in a physiological manner and the well known response to single or intermittent injections is so great as to virtually reverse the currently accepted picture of parathyroid hormone as an agent of bone destruction. The evidence indicates rather that its physiological role may be to promote calcium retention and bone formation and focuses attention on earlier studies in which PTH given chronically to rats in low dose was shown to have an anabolic effect on bone^{27–29}.

This conclusion has clinical implications of two kinds. Pathologically, the qualitative difference between high-dose and low-doses responses to parathyroid hormone implies that the syndrome of hyperparathyroidism may need to be subdivided. The demineralising condition currently regarded as typical may result only when there is gross over-secretion by the gland³⁰, though it will be difficult to prove this until radioimmunoassay findings can be translated into circulating levels of bioactive PTH. Manifestations of milder forms of the disease, including the frequent formation of renal calculi, are probably much influenced by the dietary levels of calcium and vitamin D (ref. 31), but it is particularly interesting that there is evidence for general or localised increase in bone density in some cases of

primary³² and secondary³³ hyperparathyroidism. Therapeutically, the present study strengthens the case for clinical trial of parathyroid hormone in osteoporosis, alone or in combination with calcitonin³⁴. As it seems that the renal and intestinal effects of parathyroid hormone can be obtained at a dose level which does not significantly increase bone breakdown, low doses may be capable of inducing a positive calcium balance and enhancing bone formation.

Finally, the importance of close attention to physiological dose levels and entry rates in future studies of hormone action can be briefly illustrated from other recent findings. The very name 'vasopressin', commonly used as a synonym for antidiuretic hormone, provides an example of a misleading physiological conclusion reached on the basis of inappropriate dosage. The word suggests a vasoconstrictor and pressor agent, yet pressor effects are first seen after doses of $10\text{--}40 \mu\text{g}$ ($5\text{--}20 \text{ U}$) in man³⁵, which must produce blood levels of several ng ml^{-1} . The normal blood level of this hormone is known now to be about 4 pg ml^{-1} ($2 \mu\text{U ml}^{-1}$), rising to 40 pg ml^{-1} during water deprivation³⁶. At this concentration, the hormone seems to act exclusively on the kidney. The need to imitate physiological entry rates was also illustrated by work of Knobil and his colleagues^{37,38}, showing that the 'pre-ovulatory' surge of luteinising hormone can be triggered by a small dose of oestrogen in ovariectomised monkeys. There was no dose which would produce the response unless a physiological basal oestrogen level had been established during the previous week by subcutaneous injections of oestrogen in oil or implanting crystals in a slow-release capsule.

Insulin is another hormone with a wide variety of dose-related effects and it may be that the incidence of pathological changes in chronically maintained diabetics could be greatly reduced by imitating physiological blood levels more closely than the depot-insulins permit.

Parathyroid hormone was prepared from fresh-frozen beef glands in the large scale laboratory of the National Institute for Medical Research. We thank Dr J. L. H. O'Riordan, Middlesex Hospital, for assistance in the final stages of its purification and the Armour Pharmaceutical Company, Eastbourne, who provided facilities for sterile ampouling.

received the same volume of vehicle alone. Injections were given from day 7 of gestation, at the time of formation of the neural tube, until day 20 when each pregnant rat was injected intraperitoneally with 500 μ Ci of tritiated thymidine (3 H-TdR). Neurones in the cerebral cortex were labelled specifically by administration of 3 H-TdR at the time of their origin on day 20 of gestation². The rate of

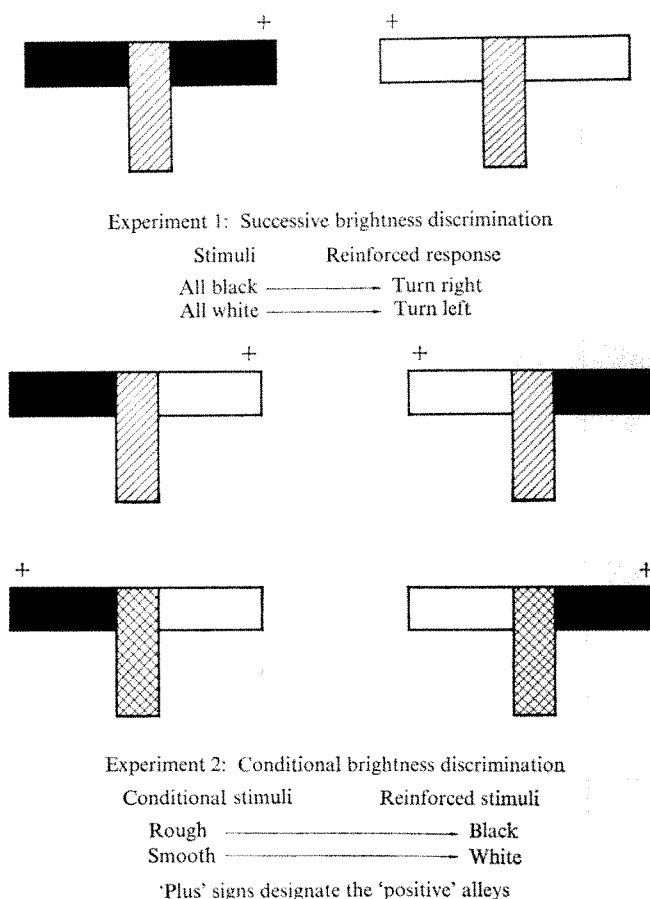

Fig. 2 Procedures used in the conditional discrimination tasks. Experiment 1: successive brightness or spatial conditional discrimination where the animal is trained to turn right for reinforcement when both arms are black, and left when both are white. Experiment 2: brightness conditional discrimination where the animal is trained to turn to the black arm for reinforcement when the floor of the alley is rough, and to the white arm when the floor of the alley is smooth. +, Denotes the positively reinforced discriminanda and the cross-hatching of the alley arm represents the rough tactile stimulus.

Prenatal action of growth hormone on brain and behaviour

IMPLICIT in all physiological theories of learning is the concept that learning ability depends on neuronal interaction, a function of both the number of neurones and the extent of their interconnections. Although learning ability varies with axo-dendritic development¹, a similar relationship to neuronal number has not been demonstrated, possibly because neuronal proliferation in most species, including rat² and man³, has ceased *in utero*. As alterations in neuronal number must therefore occur before birth we hypothesised that any prenatal growth factor would increase the number of cortical neurones and enhance subsequent learning ability. We have investigated this question, using young rats which had received pituitary growth hormone as the prenatal growth stimulus.

The experimental procedure is summarised in Fig. 1. Pregnant Wistar rats were treated at random in one of five ways: experimental animals received daily subcutaneous injections of either 3 mg, 1 mg, 100 μ g or 10 μ g of purified porcine growth hormone (0.6 U mg⁻¹) and controls

Table 1 Effect of various doses of growth hormone on brain structure and learning ability

Group	Brain weight* (mg)	³ H-TdR uptake* into brain DNA (d.p.m.)	Packing* density (d.p.m. mg ⁻¹ of brain tissue)	Number of trials† to obtain criterion performance on the first behavioural task‡	Number of trials† to obtain criterion performance on the second behavioural task‡
Control	387 ± 81	14,497 ± 4,763	43 ± 15	36 ± 12	88 ± 25
